7710 and 7711, *ibid*, to revoke a license to practice, seeks to regulate the practice of licentiates by stating as a cause for revocation "unprofessional conduct" and enumerating certain types of conduct that are embraced in the term, it is significant that there is not there included within such an enumeration of prohibited conduct practice for gain as the employee of an unlicensed individual or corporation. The conclusion seemed irresistible to the court that by the medical practice act the legislature intended to prevent unlicensed persons from the actual diagnosis and treatment of human ills but did not intend to prevent unlicensed persons from engaging in the business of supplying the services of licensed practitioners. The prevention of corporate practice the court accordingly held, was not in the contemplation of the legislature when it enacted the medical practice act, and the corporation here involved, in contracting with the county, did not bargain to do that which is prohibited by the medical practice act.

To sustain the judgments adverse to the corporation, the county next contended that the practice of medicine by a corporation through the agency of employees who are licensed to practice medicine is illegal because it is against public policy or public interest and a corporation so practicing is not entitled to recover or retain compensation for its illegal acts. Public policy, said the court, is that principle of law which holds that no person can lawfully do that which has a tendency to be injurious to the public or to be against the public good. 17 C. J. S. 563. When conduct opposed to the public interest is made the subject of a bargain, the courts ordinarily refuse to accord a party thereto a remedy predicated thereon. Restatement, Law of Contracts, sec. 598. The subject of the practice of the learned professions by a corporation has been under consideration by the courts in a variety of actions and proceedings involving the practice of law, dentistry and medicine. See annotations in 73 A. L. R. 1327 and 103 A. L. R. 1240. While decision has rarely turned on the naked issue of public policy, those courts, by dictum at least, indicate a current of opinion, to which there are but few dissentients, that the corporate practice of the learned professions contravenes the public interest and is contrary to public policy. After discussing the variety of reasons assigned therefor, the court concluded that the corporate practice of any of the learned professions of law, medicine or dentistry would tend to debase those professions and that corporate practice would have a tendency to blight the character or lower the standards of professional practice and would be in contravention to the public aspirations so clearly reflected in the licensing statutes, which, with their emphasis on character and professional conduct on the part of licentiates, evidence a fixed public desire not only to foster but to develop and reinforce the basic attributes of the professional servants of the public. The court was of the opinion that the practice of the learned professions by a corporation organized for profit, even though it functioned through duly licensed physician employees, tended to debase the profession and consequently was in contravention of the public interest and was against public policy. The contracts, the court held, between the corporation and the county with respect to the rendering of medical and surgical services were illegal and the corporation can recover nothing for the services it rendered under those contracts.

The court next considered the legality of the contracts between the corporation and the county under which the corporation undertook to supply medicines and drugs to the county poor. The corporation was not licensed to practice pharmacy, but the medicines involved were prescribed by physician employees of the corporation in the course of the practice of medicine. The pharmacy practice act provides that nothing therein contained shall apply to the business of any physician or prevent him from supplying to his patients such articles as may seem to him proper. Session Laws, 1933, chapter 163. The pharmacy practice act, said the court, clearly intended to

exclude the practice of medicine from its regulatory effects. However, while thus removing the subject matter of these contracts from the scope of the pharmacy practice act, the act did not authorize the sale of medicines by a physician in any other manner than as an incident of the practice of his profession. Medication is but an integral part of the services a physician performs in treating human ailments, and the right to furnish medicine rests on the right to treat disease. It follows then, that, if it is against public policy for the corporation to engage in the practice of medicine, all of the incidents of that practice by the corporation, including medication, are contrary to public policy. The court accordingly held that that contract between the corporation and the county under which the corporation undertook to supply medicines to the county poor was illegal and that the corporation could recover nothing for its acts thereunder.

The court next considered the right of the county to recover sums previously paid to the corporation for medical and surgical services and medicines supplied to the county by the corporation. The county, said the court, while it seeks to recover the payments made to the corporation for those services and supplies, endeavors to retain the benefit of the valuable professional services and medicines it has received. It predicates its right to a refund of such payments on the theory that the bargains under which such payments were made were against public policy. It contends that it may appropriate these benefits and recover its payments. Obviously, the claim of the county is inequitable. Manifestly, justice will not be done if the county is permitted to recover its payments and retain the valuable benefits it received under the illegal contract. Had it not received the benefits of the services of the duly licensed employees of the corporation it would have been compelled to expend public funds for like services elsewhere. In procuring the needed services public policy was violated. The subject matter of the contract was not vicious in itself, and no moral turpitude was involved. The public interest is adequately and effectively protected by the obligations of a judicial policy under which the courts refuse to lend themselves to that which is against public interest. Considerations based on natural justice may be permitted to mold the judgment in this particular case without withdrawing any public safeguard or striking down any provision adopted to protect the county or its taxpayers. In our opinion, no circumstance warrants or supports a contention that, according to the ties of natural justice or for reasons based on public policy, the corporation should be obligated under the circumstances to refund to the county the monies paid to the corporation for valuable services and supplies rendered to the county. The court accordingly reversed the judgment of the trial court and held, in effect, that the corporation might retain the monies paid to it by the county — *Bartron v Codrington County (two cases) and Codrington County v Bartron (Bartron, Intervener)*, 2 N. W. (2d) 337, (S. D., 1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1933 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 16 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Clinical Pathology, Baltimore 13 383 440 (Aug) 1943

Cerebral Injuries by Mechanical Violence S A Levinson—p 402

Thallium Poisoning III Clinical Toxicology of Thallium A O Gettler and L Weiss—p 422

Transfusion in Acute Hemolytic Anemia of the Newborn—Wiener and Wexler state that in the typical case of acute hemolytic anemia of the newborn the mother is Rh negative, the father is Rh positive and the fetus is Rh positive, the latter having inherited the factor from the father. Owing perhaps to some defect in the placenta, some of the fetal blood escapes into the maternal circulation, and in sensitive mothers this stimulates the production of anti Rh isoantibodies. Since the normal placenta is permeable to antibodies, the anti Rh isoantibodies then filter back through the placenta into the fetal circulation and give rise to the disease. In the past, infants with acute hemolytic anemia were treated by repeated transfusions with varying results. The theory of Levine et al makes possible a more rational transfusion therapy. Whole maternal blood should not be used because in this way additional isoantibodies may be transferred to the infant and thus prolong the disease. For the same reason the baby should not be permitted to nurse as antibodies may be transferred through the colostrum and milk. Also the father or any Rh positive donor should not be used, since the erythrocytes of such donors are susceptible to the action of the anti Rh antibodies. The most suitable donor is a normal Rh negative individual, because his cells are not sensitive to the action of the antibodies and his serum contains no anti Rh isoantibodies. The authors describe 8 cases of acute hemolytic anemia of the newborn recently treated by them. The disease is a treacherous one in that the baby may appear normal at birth and yet develop an abrupt hemolytic crisis which may cause death from anoxemia in a short time. As soon as the diagnosis is made or even suspected, arrangements should be made for immediate transfusion with Rh negative blood. Only intravenous transfusions are effective. Though transfusions in infants are technically difficult, in trained hands the procedure is carried out with ease with the aid of a small, short bevel 22 gage needle, using a scalp vein. In infants whose scalp veins are poorly developed or concealed by edema a suitable vein can as a rule be found by making an incision anterior and superior to the medial malleolus or by incising the antecubital fossa. The authors mention atypical cases due to sensitization to factors other than Rh or due to multiple sensitization. They suggest transfusion with washed mother's erythrocytes suspended in compatible plasma.

Comparison of Techniques for Differential Counting of Bone Marrow Cells (Guinea Pig) R D Epstein and Edna H Tompkins—p 249

Ophthalmology Toxic Effects of Sulfonamides on Eyes H P Wagener—p 261

Transmissibility of Malaria by Plasma Transfusions—Lozner and Newhouser report the results of thirty-five administrations of plasma prepared from donors with active malaria and preserved by different techniques for varying lengths of time. The donors were patients with active therapeutic quartan and estivoautumnal malaria. The 35 recipients were patients with dementia paralytica or other central nervous system disease in which malaria was either indicated or not contraindicated. No transmission of malaria was observed in twenty administrations of thawed plasma which had been "shell" frozen in a solidified carbon dioxide-alcohol bath. In three administrations of restored plasma which had been dried from the frozen state no transmission took place. In two administrations of plasma preserved in the liquid state for one day there was one definite transmission and one probable transmission. In five administrations of plasma preserved in the liquid state for one week there was one doubtful transmission. In five administrations of plasma preserved in the liquid state for two weeks no transmissions were recorded. The likelihood of transmission of malaria by any plasma program regardless of type of preservation used is practically nonexistent.

Patent Ductus Arteriosus—Shapiro and Keys investigated the longevity and cause of death in untreated and surgically treated patients with patent ductus arteriosus. Diagnosis of patent ductus arteriosus can be made with much certainty. The great majority of patients with this defect suffer no serious disability or restriction of activity during most of their lives, but their life expectancy is greatly shortened by the defect. Ligation of the uninfected ductus can be made with a mortality of less than 10 per cent. Ligation of the ductus in the presence of subacute bacterial endarteritis offers an even chance of survival in the face of practically certain death without ligation. The danger of development of subacute bacterial endarteritis after successful ligation cannot be properly estimated. Six case histories are cited which illustrate arguments for and against ligation. An analysis is presented of the results of one hundred and forty operations for ligation of the duct. The majority of patients with patency of the ductus arteriosus should be submitted to ligation after careful clinical studies have been made on them. Ligation should be attempted immediately if subacute bacterial endarteritis develops. Ten patients with uninfected patent ductus arteriosus have been operated on.

by Wangensteen at the University of Minnesota Hospital, the last 8 cases with complete success. None have manifested a recurrence of signs indicating recanalization.

Clinical Significance of Hyperventilation—According to Stead and Warren, respiration is controlled by both reflex and chemical mechanisms. Afferent stimuli from any organ in the body or from an emotional content of thought may cause the pulmonary ventilation to be increased beyond the level required by the body metabolism. This reflex increase in respiration furnishes the physiologic basis for many of the symptoms of the psychoneurotic patient. The patient may be conscious of the hyperventilation and complain primarily of dyspnea or he may complain of any of the resultant symptoms, not being aware of the increased pulmonary ventilation. The authors give several illustrative case reports. Voluntary hyperventilation in normal subjects produces a disturbance in cerebral metabolism. Usually faintness or giddiness is followed by numbness and tingling about the mouth and extremities, the hands become cold, and if the patient is standing he may faint. Prolonged hyperventilation may produce symptoms of tetany. Any of the cerebral symptoms produced by voluntary hyperventilation may appear in the anxious patient who unknowingly hyperventilates. Production of these symptoms by voluntary overbreathing not only is of diagnostic aid but is useful in demonstrating to the patient that his symptoms have a physiologic rather than a pathologic basis. At times the hyperventilation itself may be noted by the patient and may appear as a symptom, particularly in patients with heart disease without congestive failure or in patients who fear heart disease. Observation of the effects of voluntary hyperventilation should be a routine procedure in the examination of (1) patients complaining of fainting, giddiness or a far away feeling and (2) patients with breathlessness, particularly those with heart disease without evidence of congestive failure.

Sulfamerazine in Meningococcic Meningitis—Sulfamerazine is one of several methyl homologues of sulfadiazine. Geffer and his associates used sulfamerazine for meningococcic meningitis during an epidemic of that disease in Philadelphia in the past winter. They report observations on 45 cases. The initial dose was always given intravenously as sulfamerazine sodium (5 per cent solution in sterile distilled water), adults receiving 3 Gm and children 1 to 2 Gm. This dose was immediately followed by sulfamerazine orally, adults receiving 1 Gm every four hours and children receiving 0.25 Gm to 1 Gm every six hours. Delirious or comatose patients were given the drug by nasal tube until they were capable of taking medication by mouth. Sulfamerazine was continued until the patient appeared entirely well clinically. In the successfully treated group the average total dose of the drug for adults was 56.4 Gm, given over an average period of 9.5 days, the children received an average total dose of 19.3 Gm over an average period of 8.6 days. Five of the patients were given intravenous antimeningococcus serum in addition to sulfamerazine. Determinations of the amount of free drug in the blood were made at frequent intervals. Three deaths occurred in this series, a mortality of 6.7 per cent. This is to be compared with the 57.5 per cent mortality occurring in 40 cases of this disease at the Philadelphia General Hospital during 1935, 1936 and 1937, and with the 40 per cent in 50 cases reported in 1942. The results also compare favorably with those in which sulfadiazine was employed (12.5 per cent mortality). Clinical improvement with return of mental clarity occurred in 70 per cent of the patients within forty-eight hours. The average time observed for the return to normal temperature was 5.2 days. Toxic reactions attributable to sulfamerazine, occurring in each instance after the fifth day of treatment, were noted in 11 patients.

Sulfamerazine in Pneumococcic Pneumonia—Flippin and his collaborators compare the response to sulfamerazine of 80 pneumonia patients with that of a control series of 80 adult patients treated with sulfadiazine. Mortality in the two groups showed no significant difference (sulfamerazine 7.5 per cent, sulfadiazine 10 per cent). Sulfamerazine tended to lower the temperature somewhat more rapidly than did sulfadiazine, however, the duration of chemotherapy and the incidence of

complications were essentially the same for the two groups. The incidence of toxic reactions was low and comparable for both sulfamerazine and sulfadiazine. No serious reactions were encountered with either drug. The fact that toxic reactions were less frequent among these pneumonia patients than among those receiving sulfamerazine for meningitis is explained by the fact that medication was of shorter duration. The group treated with sulfamerazine showed higher plasma concentration of free drug than did the group receiving larger or equivalent amounts of sulfadiazine.

Rickettsial Vaccine as Antigen in Complement Fixation Test—According to Reynolds and Pollard the Weil-Felix reaction lacks specificity in the diagnosis of rickettsial infections, while the complement fixation test is rather specific in differentiating them. The complement fixation test uses antigens prepared from infected chick embryos. The commercially prepared typhus vaccine is similarly manufactured from infected chick embryos. The authors found that a commercially processed typhus vaccine is satisfactory for fixing complement with epidemic typhus antiserum. Its specificity was supported by negative results with the following heterologous specific antisera: Rocky Mountain spotted fever rickettsia, *Proteus* OX 19, *Eberthella typhosa*, *Salmonella typhi* murium, *Salmonella paratyphi*, *Salmonella schottmülleri*, *Salmonella pullorum*, *Salmonella enteritidis*, *Salmonella paratyphenteriae*, *Salmonella abortus-equinus*, *Pasteurella tularensis*, *Vibrio comma*, *Brucella abortus*, *Brucella melitensis*, *Trypanosoma equiperdum* and *Trypanosoma cruzi*. Of 89 positive Wassermann and Kahn serums tested, one induced a 3 plus fixation with both the commercial purified antigen and the typhus vaccine. This one case gave a history suggestive of a typhus like disease several years prior to the test. Thirty-two persons were given three subcutaneous injections of commercially prepared typhus vaccine of 1 cc each at weekly intervals. On the twelfth day following the last inoculation blood serums were collected from all of them and tested with both antigens. None demonstrated evidence of complement fixing bodies for typhus. Apparently the chick embryo menstrium in which the Rickettsiae were growing failed to induce homologous complement fixing bodies in persons injected with it. The absence of complement fixing antibodies does not necessarily imply a lack of immunity, it does demonstrate that the vaccination procedure will not result in the development of a false positive reaction.

American Review of Tuberculosis, New York

48 65 130 (Aug) 1943

Culturing of Tubercle Bacilli from Human Spleen, Liver and Kidney—Woodruff and his co-workers took cultures of human necropsy material in order to determine the number of tubercle bacilli per gram of tissue in spleen, liver and kidney. In a large majority of the cases cultures of the spleen were found positive for tubercle bacilli. A smaller proportion of liver cultures and even fewer of the kidney cultures were positive. A rather close correlation was found to exist between positive culture and microscopically demonstrable tubercles in the same organ. A high bacterial count was associated with the type rather than the number of tubercles the

highest counts being found in those organs which had caseous miliary tubercles. The number of tubercle bacilli found per gram of splenic tissue was nearly always greater than the number of bacilli in liver and kidney. The only exceptions were cases with extensive tuberculous enteritis or other abdominal tuberculosis. In these cases the liver contained more tubercle bacilli than the spleen.

Hemorrhage in Pulmonary Tuberculosis—Minor collected data for this study from the records of 1,000 sanatorium patients. He found that hemorrhages occurred in 24.3 per cent. The average size of hemorrhage was 5 ounces (150 cc). Forty per cent of hemorrhages eventually recurred. In 60 cases the first remarkable symptom was hemoptysis. Seventy per cent of cases with a history of hemorrhage before the diagnosis were properly diagnosed by the local physician when he was consulted. However 13 per cent were misdiagnosed. Most tuberculous patients who have a hemorrhage have a cavitation visible on x-ray examination, 83.4 per cent of this series had a positive sputum. Trauma to the chest, strenuous exercise, mechanical disturbance of the lungs and, in females, the menstrual period are definite precipitating factors. Small hemorrhages often occur from early lesions at the height of the catarrhal and toxic symptoms, which probably signify softening. These are not usually serious and may in the long run be beneficial if they call attention to an undiagnosed tuberculosis. However larger hemorrhages which occur in chronic ulcerative tuberculosis, while rarely immediately fatal, are accompanied by many unpleasant and dangerous possibilities. Of the twelve deaths which occurred in the Blue Ridge Sanatorium of Charlottesville, Va., after hemoptysis it was felt that five were directly or indirectly the result of the hemorrhage.

Dupuytren's Contracture as Sequel to Coronary Artery Disease—Kehl reports 6 cases of Dupuytren's contracture as a sequel to coronary occlusion. The palmar changes in the cases presented by Kehl appear to be typical of Dupuytren's contracture in its various stages. Three cases progressed to the stage of contracture and in no case was regression noted. Pain, stiffness, swelling, livid discoloration, numbness, tingling and abnormal skin temperature of the hands may be associated with the palmar changes. The etiology and pathogenesis are not understood but irritation of the sympathetic ganglions may assume an important etiologic role.

Early Recognition of Cardiovascular Syphilis—Dressler and Silverman report studies in 1,270 cases of proved syphilis which were referred for cardiovascular checkup. There were 390 cases of cardiovascular syphilis and 304 of these were diagnosed as uncomplicated syphilitic aortitis. The authors answer in the affirmative the question whether a clinical diagnosis of uncomplicated aortitis is impossible in the presence of a normal sized aorta. They establish the following criteria for clinical diagnosis in patients 40 years of age or younger: 1. The presence of a characteristic aortic second sound which may be described as tambour, drumlike, tympanic or hollow and is usually heard over the second or third right sternal space and sometimes over the fourth space. 2. The presence of a

systolic murmur over the aortic area (second, third or fourth right sternal space, over the sternum, the third left sternal space or in more than one of these areas). A systolic murmur has been heard in many instances over the mitral area. 3 The presence of suprasternal (episternal) pulsations. This sign indicates elongation and dilatation of the aortic arch. 4 The presence of increased retromammary dullness in the second intercostal space. This sign is of value only when the aortitis is far advanced and there is a widening of the aorta. 5 The presence of hypertension is a diagnostic aid. Both systolic and diastolic pressures are elevated. 6 Corroboration of the clinical findings by the use of fluoroscopy and roentgenography to demonstrate the presence or absence of a widened aorta. All patients with cardiovascular syphilis should be started with a preparatory course of bismuth compounds and iodides before arsenical therapy is attempted. This course should consist of at least ten to twelve intramuscular injections of bismuth subsalicylate in oil (0.1 to 0.2 Gm.) at weekly intervals followed by a similar course of neosphenamine (0.1 Gm.) or mapharsen (0.01 Gm.), the dosage being gradually increased. With the exception of cases of uncomplicated syphilitic aortitis, the dose should not exceed 0.3 Gm. of neosphenamine or 0.03 Gm. of mapharsen in any cardiac condition. Arsphenamine should never be used in the treatment of cardiovascular syphilis. The treatment should be continuous for at least two years. The serologic reaction should have no bearing on the length and type of treatment. If sufficiently improved, the patient is given a rest period of six months and asked to return for a cardiovascular checkup. If the patient has developed aortic insufficiency or aneurysm treatment must be more conservative. The preliminary bismuth and iodide therapy is started, but the arsenicals must be used with caution and in many instances they should be avoided. The life expectancy of patients with uncomplicated syphilitic aortitis who receive early and adequate treatment is a normal lifetime, whereas for patients who show complicated cardiovascular syphilis it ranges from about one to ten years.

Rupture of Aortic Aneurysm into Pulmonary Artery

—Nicholson stresses that the rarity of rupture of an aortic aneurysm into the pulmonary artery is unusual in view of the close anatomic relationship between the two vessels and the great frequency of aneurysm of the thoracic aorta. Only 81 instances have been mentioned in the literature. This low incidence may be explained on the basis of pinpoint communications between the great vessels, oversight on the part of the pathologist and failure to appreciate the condition clinically. Over a thirty year period only 2 instances were observed at the Charity Hospital of Louisiana in New Orleans. One occurred in a 39 year old woman who survived five months after rupture, and the other in a 40 year old man whose duration of life following rupture was six days. Both instances were diagnosed correctly prior to death. The author reviews the incidence of clinical manifestations which might serve for recognition of the syndrome. The history reveals a sudden onset with severe stabbing pain or a sense of oppression in the precordial area with or without radiation, usually following physical exertion and succeeded by pronounced and increasing dyspnea. The subjective signs are definite and increasing shortness of breath, progressive swelling of the lower extremities and trunk, rasping cough with expectoration or hemoptysis and bluish discoloration of the face and extremities, pallor may be the alternative. The objective signs are an intense thrill in the second to third left interspace occurring during systole or continuous throughout the cardiac cycle, humming "machine-like" murmur, heard best to the left of the sternum in the second or third interspaces, continuous throughout the systolic and diastolic phase and crescendo-decrescendo in character, being more intense during systole, evidence of aneurysm of the aorta increasing dyspnea usually reaching the extent of orthopnea, cyanosis of the lips, face or extremities or distinct pallor of the same areas, edema of the lower extremities and trunk progressing to anasarca, the hemodynamic phenomena of aortic regurgitation (Corrigan's pulse, increased cardiac rate, capillary pulsation, Duroziez's sign), roentgenographic evidence of aneurysmal dilatation of the aorta, prominent and enlarged pulmonary conus and probable enlargement of the heart, electrocardiographic

indications of a nonspecific character but usually indicative of a sinus tachycardia, right axis deviation, and lowering, inversion or diphascity of the T waves in the standard and precordial leads.

Prevention of Infection in Contaminated Accidental Wounds—Meleney summarizes records from 1,500 cases which include 682 wounds of the soft parts, 471 compound fractures and 347 burns. Studies had been carried out by a number of different units to establish the effect of the sulfonamides on accidental wounds. There was no evidence that either sulfanilamide or equal parts of sulfanilamide and sulfadiazine locally or sulfadiazine generally with or without the local use of drugs have cut down the incidence of local infection in wounds of the soft parts. It is true, however, that the incidence of septicemia or of death is extremely low in this series and it may be stated that the spread of infection from the local site has been minimized. The combined local and general use of sulfonamides alone has not lowered the incidence of local infection in compound fractures. Although there were only 2 patients who died as a result of infection, and these yielded no positive blood cultures, a fair number of patients needed secondary surgical procedures because of wound infection. The infection rate in burns is very disturbing, particularly in the deep second and third degree cases. There is evidence that there may be greater or less absorption of the drugs from burned surfaces according to the vehicle in which the sulfonamide drugs are contained. The ideal vehicle has not been found. Many are being tried. The local drug action may be inhibited while the general effect may be obtained from local applications. There were only two burn deaths in which infection played an important part and these were so extensive that death might have occurred without infection. In both local and general sulfonamide treatment was administered. The author concludes that the sulfonamides minimize the general spread of infections and cut down the incidence of septicemia and death. There is no evidence that they lessen the incidence of local infection.

Protein Nutrition in Burned Patients—Taylor and his associates studied the problem of protein metabolism in burned patients. Hypoproteinemia occurred frequently in a series of 63 patients. In some, hypoproteinemia was fugitive and was probably associated with early loss of plasma. In other it persisted but later responded to high protein diets of 3000 calories which contained from 100 to 125 Gm. of protein per day and were supplemented with 25 to 30 Gm. of brewers yeast and other vitamin supplements. Other patients did not respond to such diets or could not ingest them. This group was composed of the most severely burned and in them the hypoproteinemia became progressive and often reached the fatal level. A detailed study of nitrogen metabolism has been reported on a patient with a burn of 55 per cent of his body surface.

Similar studies have been made on 9 other patients. In severely burned patients there appears to be an excessive loss of nitrogen into the urine in addition to large losses of nitrogen by exudation from the burned surface and an increased nitrogen demand for the building of new tissue. Studies on the patient revealed that nitrogen balance determinations based on urine and stool analyses together with known nitrogen intake cannot reveal the considerable nitrogen loss from the burned surface and the demand for building new tissue. On a high protein diet alone this patient developed a protein deficit of 2000 Gm. The patient's edema increased and it was not until a total nitrogen retention estimated at over 6000 Gm of protein had been obtained that the edema was completely relieved and good nutrition obtained. At least 6000 Gm of protein was required over and above that indicated by balance studies. In some severely burned patients positive nitrogen balances will be found impossible to maintain from diets alone. In such an event forced alimentation by intubation or by the intravenous administration of amino acids should be attempted as soon as possible. Such protein deficits cannot be replaced by whole blood or plasma transfusions, since it would be necessary to administer 120 liters of plasma to accomplish the equivalent of the supplementary alimentation given. At present the only satisfactory way is forced alimentation by intubation and amino acid administration by vein with proper precautions.

Amino Acids, Serums and Plasma in Replacement Therapy of Fatal Shock—Elman and Lischer describe hemorrhage in which replacement of the lost blood by an amino acid mixture seemed to have a beneficial effect. The approach has been biochemical rather than physical or physiologic. This is emphasized because amino acid mixtures cannot be regarded as blood substitutes since they lack the colloidal properties of blood plasma. The value of such injections must depend on the ability of the body to use amino acids to synthesize plasma proteins rapidly or for nutritive or other metabolic purposes. It is theoretically possible for injected amino acids to be made into plasma proteins rapidly and thus act as an indirect substitute or supplement to plasma. The liver is the key organ in this process. Fatal surgical shock in unanesthetized dogs followed bleeding 10 cc per kilogram of body weight every hour, the mean survival time being 36 hours. There was a progressive fall in the blood pressure in the red cell volume and in plasma albumin and globulin in all experiments. If the blood removed each time was immediately replaced by the same volume of various solutions, significant differences were observed as follows. The survival time was unchanged with dextrose in saline solution, was increased to 42 hours with pure amino acids and was increased to 515 with hydrolyzed protein. With citrated plasma or serum survival time was but 45 and 46 hours, whereas with heparinized plasma it was 60 hours. The fall in blood pressure was greater with citrated plasma and serum than with heparinized plasma, whereas hydrolyzed protein produced less hypotension than dextrose. Study of the changes in red cell volume and in plasma proteins gives some indication that the amino acids of hydrolyzed protein were converted into plasma albumin. Microscopic study of the liver suggests that protein is lost from the hepatic cytoplasm in hemorrhage and that injecting hydrolyzed protein replenishes this loss as compared with experiments in which dextrose was used. It may be inferred that in shock due to repeated hemorrhage a solution containing amino acids and peptides of hydrolyzed protein has a beneficial influence as compared with dextrose and that heparinized is far superior to citrated plasma.

Traumatic Shock—Tine and his co-workers report a study on the capillary leakage hypothesis in shock utilizing radioactively tagged plasma proteins. By tagging the plasma protein molecule with a radioactive element and introducing such plasma protein into the blood stream a label is provided by which to identify the movement of plasma proteins. In order to obtain as physiologic a preparation as possible, radioactive cystine was synthesized from radioactive sulfur (eighty day half life) and was fed to plasma protein deficient dogs, which incorporated the cystine into their own plasma proteins. Plasma protein removed from these dogs was then administered to normal dogs and to dogs shocked by hemorrhage and its rate

of escape from the circulation determined. Plasma proteins tagged with radioactive isotopes (S^{35} , Br^{82} , I^{131}) were used to study the capillary leakage hypothesis in hemorrhagic, tourniquet and burn shock. No evidence of leakage due to a change in the permeability of the general capillary bed was found. Tagged plasma proteins escaped into areas of injury in considerable amounts but not into untraumatized areas. There is no evidence to show that the general capillary bed becomes more permeable to plasma proteins or plasma in the late or irreversible phase of shock. Data obtained by the use of radioactively tagged red cells injected intravenously combined with tissue analyses for hemoglobin and tagged red cell content indicate that about one fifth of the capillary blood becomes stagnant or trapped out of active circulation as the shock phase deepens. The progressive decline in shock is not due to a fall in plasma volume but to a fall in the volume of actively circulating plasma. The blood content per gram of tissue is not more and is generally the same, or less in shock than it is in normal dogs. The therapeutic problem in shock after adequate replacement of lost blood or plasma has failed is one of restoring volume and velocity flow through capillaries before the integrity of vital tissue processes is lost.

Azosulfamide and Phenobarbital in Epilepsy—According to Cohen and his associates, azosulfamide has been demonstrated to exhibit anticonvulsant action in patients with epilepsy. Associated with the anticonvulsant effect are alterations in the concentration of chemical constituents of the serum were described. These included a decrease in the carbon dioxide content of the serum, a decrease in the carbon dioxide combining power of the serum and an elevation in serum chlorides. The authors investigated the nature of the metabolic changes associated with ingestion of azosulfamide and with phenobarbital, a drug with anticonvulsant properties. Administration of azosulfamide is accompanied by a decrease in the carbon dioxide content and the carbon dioxide tension of the serum. The decreased carbon dioxide content and the lowered carbon dioxide tension of serum accompany the anticonvulsant effect. The anticonvulsant effect of both azosulfamide and phenobarbital coincides with a positive potassium balance. Ammonium chloride produces the same degree of 'acidosis' as does azosulfamide without alteration of potassium exchange and does not have an anticonvulsant effect. Phenobarbital produces no 'acidosis' but a positive potassium balance and has an anticonvulsant effect. This suggests that 'acidosis' is not necessarily the crucial factor in anticonvulsant action.

Vaginal Smear in Diagnosis of Uterine Cancer—Papanicolaou discovered in the course of routine studies of human vaginal smears not only that the normal cells were shed but that many pathologic cells could be found, among them those of cancer. Papanicolaou and Traut studied thousands of vaginal smears in an attempt to determine the incidence of cancer cells in the vaginal smear as related to the incidence of malignant disease in the uterus as demonstrable by clinical methods and biopsy technique. The malignant epithelial cells exfoliate from the surface of neoplastic growths much as do normal cells. They float downward into the vaginal fornix, where they accumulate and become mixed with normal cells of epithelial and blood origin, as well as with mucus, bacteria, parasites and cellular debris. The rate of exfoliation of malignant cells seems to be dependent on the rate of growth of the neoplasm and its size. Meticulous scrutiny of the stained smear preparations is an important essential. The vaginal smear presumptive diagnosis should be substantiated by biopsy. The value of the vaginal smear in the diagnosis of cancer of the uterus is that it can be applied to larger numbers of women because of its simplicity and ease of application. The vaginal smear may be made without trauma and thus the danger of dissemination by way of open lymphatics is avoided. The authors found in the course of several thousand examinations 193 instances of carcinoma of the uterus—about 126 lesions involving the cervix and of both the squamous and the adenocarcinomatous types, the remaining 67 were carcinomas of the fundus. The smear showed the presence of cancer of the cervix in all but 13 per cent of instances when it was demonstrable by biopsy. Thirteen instances of adenocarcinoma were revealed for the first time by the vaginal smear when no other clinical procedure had sufficed to make the diagnosis. Some of these were early lesions.

Immunization Against Influenza A—Hare and his associates state that a vaccine made by concentrating the virus in allantoic fluid according to the method of Hare, McClelland and Morgan is strongly antigenic and that the serum taken after immunization has a high titer as measured by the agglutinin inhibition test. The levels reached are as high as those reached by patients convalescing from the disease. But whether the immunization had conferred actual immunity cannot be answered until an immunized population is subjected to an epidemic. A higher antibody level is obtained with a concentrated vaccine than with allantoic fluid which has been untreated. There was a possibility that a soluble antigen which may have been present in allantoic fluid but is removed when the vaccine is made might have been of importance. Whether one or two doses of vaccine should be given is a moot point because the increase in antibody level was in general lower when two doses were given than with only one. The reasons for this are not apparent other than the possibility that there may have been a negative phase in Wright's sense of the term. The use of the concentrated vaccine is not as yet practicable when large numbers are to be immunized. The actual process of concentration is not difficult, but the yield is small. Little more than 7 or 8 cc of fluid can be collected from each egg and if this is concentrated ten times it follows that less than 1 cc of

completed vaccine can be obtained from each egg. Unconcentrated vaccine was definitely a less powerful antigenic stimulus than the concentrated, some subjects having scarcely any rise in titer. Should the vaccine doses confer immunity, the problem would be one of production.

Digestion of Bread in Human Stomach—Pekel wheat bread made from flour containing all of the wheat kernel except the outer epidermis weighing less than 2 per cent was studied by Rostorfer and his collaborators in comparison with several other breads in experiments on gastric digestion in 6 human subjects. Samples drawn from the stomach by the Roberts tube one hour after eating were analyzed for total and free acidity, total solids, pepsin, total and free reducing sugar, and total and soluble nitrogen. Correction for time lost in sampling and for free reducing substance and soluble nitrogen in the breads made possible the calculation of rate of carbohydrate and protein gastric digestion. It was found that small extra amount of pantothenic acid (100 mg per 100 g of other B factor) contained in high vitamin breads had no effect on digestion at least as great as that obtained with the synthetic calcium salt of the acid.

does, one an hour before the test meal and the other eight to ten hours before. Another important observation was with respect to the digestion of starch in breads. The use of high vitamin yeast seems to bring the digestibility of whole wheat bread up to that of white bread. This appears to offer a clue to the preparation of a "successful" whole wheat bread, but the improvement as yet applies only to digestion of "hydrolyzable carbohydrate." Possibly the addition of nonfat milk solids would increase protein digestion (in the stomach) also to the level of that of ordinary white bread. Further experiments are necessary to clarify questions involved in the production of a wholly acceptable whole (98 per cent) wheat bread. In the gastric digests of the whole wheat bread the average pepsin content was approximately 40 per cent greater (Mett tube measurement) than in those of the two white breads. The peptogenic value of whole wheat bread, therefore, is not to blame for lower rates of protein digestion, and such error is results from the small amount of (soluble) nitrogen in the pepsin does not invalidate but rather gives emphasis to the slower rate of gastric digestion of the whole wheat product. The vital economic value of whole wheat as food for man is not touched by these facts, for the over all digestion is sufficiently high to produce a large net saving not only of protein but also of calories from the wheat for human consumption. It appears plausible that the slower rate of digestion of whole wheat in the human stomach as compared with white bread is responsible at least in part for the relative unacceptability of the former by the general public.

Attempts to Recover Poliomyelitis Virus—Toomey and his associates attempted to recover poliomyelitis virus from fruit (washings), well water, stools from sick dogs and cords from paralyzed chickens found in vicinities where human poliomyelitis had occurred. Although the virus may have been present in the specimens tested, its existence could not be demonstrated when either the eastern cotton rat or the Macaca mulatta monkey was used as the test animal.

Attempts to Isolate Poliomyelitis Virus from Urine—Toomey and his collaborators tried to demonstrate the virus of poliomyelitis in the urine of patients with bladder paralysis. Their attempt was a failure when the monkey was used as the test animal, even though such specimens were obtained at an optimal time, that is, coincident with the onset of the paralysis. Urine obtained post mortem from the bladders of poliomyelitis patients was tested for the presence of the virus on eastern cotton rats. These tests also gave negative results.

Absorption of Protein from Urinary Bladder—Baretz and his associates state that various dyes, anesthetics, drugs, urea and urinary constituents are absorbed from the urinary bladder of man, dog, cat, guinea pig and rabbit. In the present study a direct immunologic technic has been used to study the absorption of protein from the urinary bladder. Specific excitation of a passively sensitized cutaneous site was induced by oral administration of the related antigen. Studies with this method revealed that the absorption of unaltered protein occurred with physiologic regularity following oral, intraduodenal and rectal administrations of the protein and on introduction of the protein into the cervix and vagina. Experiments are described which demonstrate that absorption of traces of unaltered protein from the urinary bladder does occur. The choice of cottonseed as the antigen to be studied was determined by the availability of a serum which was particularly suitable for this purpose. This sensitizing serum was obtained from a patient with a high degree of cutaneous sensitivity to cottonseed. The uniformly positive results obtained with this simple immunologic technic in monkeys and in man clearly establish the fact that detectable traces of protein are absorbed from the urinary bladder. This organ must therefore be considered as a possible site of absorption of allergenic substances introduced into the bladder for therapeutic or diagnostic purposes. Such traces of absorbed protein are more than sufficient to produce severe reactions in individuals who are sensitive to the allergen employed. In contrast to previously reported techniques which depended on chemical tests and on delayed immunologic responses to the introduced protein the technic herein described permits almost immediate detection of the entrance of the protein into the circulation.

Postmortem Findings in Carcinoma of Prostate—Gilbert and Maigolis report a case of carcinoma of the prostate treated by transurethral resection, castration and diethylstilbestrol. This case is quite similar to the reported cases of delayed failure following castration for prostatic carcinoma. There was a temporary phase of improvement during which there was relief from pain, a decrease in the size and degree of induration of the prostate, and regression of lung metastases. This was followed by a period in which the tumor was refractive to diethylstilbestrol therapy, progressed rapidly and yet remained clinically quiescent in the prostate and in the lungs. The serum acid and alkaline phosphatase values in this case roughly paralleled the course of the disease.

Thrombin as Hemostatic Agent—Tidrick and his co-workers present a summary of clinical results obtained with the preparation "thrombin topical." Each vial contains approximately 10,000 units (the thrombin unit is defined as the amount required to clot 1 cc of standard fibrinogen solution in fifteen seconds). Thrombin has been employed in over 225 cases in the University Hospitals of Iowa City. The largest group consisted of 102 cases in which thrombin was used to control

operative bleeding from donor skin graft sites. In 27 cases thrombin has been employed in the control of operative bleeding from cancellous or cortical bone. Thrombin was used also during cholecystectomy, in the Rammstedt pyloroplasty procedure, to control oozing from mastectomy skin flaps, following biopsy or traumatic wounds in cases of blood dyscrasia, in delayed postoperative bleeding, and in miscellaneous cases of soft tissue bleeding. The use of sulfonamide drugs in the wound is not a contraindication to the simultaneous use of thrombin, nor do the drugs interfere with the hemostatic action of the thrombin preparation. Thrombin provides a useful adjunct to surgical technic. Oozing of blood from capillaries and small venules can be checked promptly whenever the bleeding surfaces are accessible. Even in the case of small arteries application of thrombin is often effective, particularly if digital pressure can be applied to the bleeding points momentarily in order to permit the clot to become firmly anchored in the tissue. There has been no evidence that the thrombin produced local irritation or that patients for whom the preparation was used repeatedly became hypersensitive to it. None of the patients showed evidence of untoward effects from absorption of the thrombin or from local thrombosis of vessels.

Unilateral Decapsulation of Kidney for Transfusion Oliguria—Flo and Cummings report a case of post-transfusion reaction which was apparently cured by unilateral decapsulation of a kidney. Since the condition was becoming progressively worse and spontaneous recovery was despaired of, they felt that a unilateral decapsulation would do less harm than a bilateral one. If a unilateral decapsulation will break the vicious chain of events, this is the procedure of choice, especially in view of the damage to the kidney such an operation must entail.

Carcinoma of Parathyroid Gland—Meyer and Ragins present a detailed account of a case of carcinoma of the thyroid gland with postmortem observations. There was only a temporary improvement in the objective and subjective symptoms following extirpation of the tumor mass some twenty-six months before death. Eight months after the operation the subjective symptoms reappeared, and a year later the fibrocystic changes of the bone became progressively worse, despite x-ray irradiation to tumor mass and bone. This was followed by a number of pathologic fractures. Six weeks before death the serum phosphorus rose to 10 mg, indicating renal decompensation. The postmortem examination revealed a recurrent carcinoma of the parathyroid gland with metastasis to the peritracheal, subclavicular and perijugular lymph nodes, the lungs and the right kidney, generalized osteitis, fibrosis cystica of the bones, bilateral nephrolithiasis, bilateral chronic ascending pyelonephritis, left pyonephrosis with atrophy of the renal cortex and nephrocalcinosis.

Hookworm Disease—Littlejohn shows that some cases of hookworm disease are mistaken for other disorders such as peptic ulcer or appendicitis, and unjustifiable operations are performed. He reviews a number of case histories in which hookworm would probably not have been discovered had it not been for making simple routine laboratory examination. He stresses that all patients with chronic pain in the upper abdomen, especially with an increase of the eosinophil count, should be examined for hookworm ova. The thymol treatment is the least toxic and the most effective.

Serologic Specificity of Autoantibody in Atypical Pneumonia.—The existence of a relationship between atypical pneumonia and the cold agglutinins was pointed out by Turner in an earlier report. More recently a comprehensive investigation of the behavior of the cold agglutinins in a variety of infectious diseases revealed the aspect which seemed to be the key to its clinical and immunologic significance. This was the demonstration that the titer of cold agglutinins for the human erythrocyte rises in atypical pneumonia during the second week after the onset of respiratory symptoms in the fashion of specific immune antibodies. Abnormal amounts of cold agglutinin developed in more than 90 per cent of a group of cases of atypical pneumonia seen in the British Isles during the winter of 1942-1943. Thus, even though the infectious agent in this disease remains unknown except in the negative sense that it is probably not bacterial, a simple serologic principle for the delineation and classification of a current type of respiratory disease has been laid down. The authors examined the cold agglutinin of atypical pneumonia for serologic specificity by the methods of selective absorption and titration of activity on the erythrocytes of several species. It was found that the agglutinin has the properties of autoantibody and reacts equally with cells representing all four major human blood groups. When isolated by absorption the autoagglutinin exhibits a limited action on the erythrocytes of lower animals, having appreciable effect on rabbit cells only. It is suggested that this specificity may be explained by the existence of a heterogenic antigen shared by man and rabbit.

Emergency Treatment of Smashed In Face. Value of Tracheotomy and Laryngotomy. D. H. Patey and E. W. Riches.—p. 161

Emergency Treatment of Smashed In Face.—According to Patey and Riches the smashed in face resulting from a severe blunt external force is emerging as a clinical entity. With the motor car and airplane as common agents in its production it is essentially an injury of modern civilization. The duties of the emergency surgeon in these cases are to deal with hemorrhage and gross soft tissue and bony damage to inspect the eyes and, if necessary, to secure the cooperation of the ophthalmic surgeon, to be on the lookout for any suggestion of cerebrospinal rhinorrhea and to administer prophylactic sulfonamides. Anesthesia of the patient with smashed in face presents difficulties. Inhalation anesthesia through a facial mask is difficult not only because of the facial injuries but because of the blood which is constantly running into the pharynx and leading to coughing and partial obstruction. If the patient is anesthetized past the stage of the cough reflex he tends to aspirate the blood into his lungs and may drown in his own blood. In this event the patient can be saved from death by asphyxia only by a rapid tracheotomy. Intravenous anesthesia might be thought to solve the difficulties, but asphyxial symptoms have been known to develop so quickly after intravenous injection that the patient's life was saved only by a rapid plunge laryngotomy. The author suggests that the initial emergency treatment of the severe types of smashed in face should be tracheotomy or laryngotomy under local anesthesia. Once an opening into the air passages has been made the anesthetic problem becomes easy, the danger of death from asphyxia is averted, and the reduction in cyanosis from the establishment of a free airway may by itself result in cessation of much of the hemorrhage.

South African Medical Journal, Cape Town

Dysentery in South Africa.—Finlayson reports that shortly after the opening of a military hospital cases of 'gas troenteritis' were observed among the patients and staff. There were two clinical types—the one type in which the patient passed from three to twenty liquid stools in twenty-four hours and after about twenty-four to forty-eight hours appeared to recover completely, the second type in which the attack was usually ushered in by violent vomiting and frequent loose stools persisting for seven or eight days. The latter type did not occur among bed patients but was noted among the staff and convalescent patients who were not confined to the hospital premises. The microscopic appearance of the stools made possible a diagnosis of bacillary dysentery long before the causative organisms were isolated. The stool examinations were

carried out by the methods described by Finlayson in 1941. It was observed that although *Bacterium sonnei* was isolated from outbreaks of dysentery occurring among the staff and from sporadic cases occurring among convalescent patients who were allowed leave from the hospital, this organism was not once isolated among patients confined to bed. In all bed patients who acquired a dysenteric infection at the hospital the organism isolated was identified as of the *Bacterium flexneri* group. The results of examinations of various foodstuffs were all negative. Since epidemiologic data pointed to milk as a possible vehicle of infection, it was examined and on four occasions bacilli with the characters of *B. flexneri* were isolated. Instructions were issued for all milk to be boiled. In spite of these instructions, cases of dysentery from which *B. flexneri* was isolated continued to occur among the bed patients. It was noted that these cases were occurring only among persons whose diet contained a high proportion of cream which was neither pasteurized nor boiled. The use of cream was prohibited, and since then no case of dysentery has occurred. Bevan in 1941 had shown that the chief cause of infantile mortality in South Africa is "infantile diarrhea." There is no doubt that this condition is a dysentery. The importance of boiling all milk unless pasteurized cannot be overemphasized. The average South African native looks on a mild dysentery as being more beneficial than otherwise. As the bulk of the milk supplies is handled by natives it is not difficult to conceive how milk can be infected by a milk handler who may be a carrier of dysentery bacilli.

Desert Sore—Vischer states that desert sore, or "Gallipoli sore," observed during the first world war in British troops in Palestine and at the Dardanelles, was seen by him recently among German and Italian prisoners of war in Egypt. These pyodermic sores resemble somewhat varicose crural ulcers except that they are found not only on the legs but also on the knees, hands, arms and the head. The sores are usually initiated by insect bites or scratches and begin as papules which become fairly large blisters containing first a yellowish and later a turbid secretion. When these blisters burst, slowly growing and profusely secreting ulcers form. The healing process is extremely slow. The sores occur chiefly during the summer, when insects are most annoying. The fact that lack of water in the desert prevents the cleansing of the sweat saturated skin is probably a factor. Troops whose general condition has been impaired by great exertion and desert heat seem to be especially subject. The native Arabs and native Libyan soldiers are free from them, they are somewhat less frequent in Italian than in German and British soldiers. The bacteriologic examination of the ulcers reveals chiefly staphylococci and streptococci and occasionally diphtheria bacilli. The diphtherically infected ulcer has a dirty gray coating and occurs as a rule only when pharyngeal diphtheria exists among the troops. Diphtherial ulcers are followed by paralysis, sometimes two or three weeks after healing. Immobilization of the involved area promotes healing of the sore. Prompt attention to small epithelial lesions prevents them. In South Africa desert sore is known under the term "veldt sore." Other terms for it are barcoo lot or septic sore.

Administration of Vitamin K in Hepatic Function Test—Armentano and Geher used Koller's vitamin K test as a test of hepatic function. In the majority of cases of obstructive jaundice the prothrombin time was restored to normal within twenty-four hours after administration of vitamin K. There were isolated cases in which the normal value could be obtained only after repeated administration of vitamin K in the course of three days. Normal values in hepatocellular jaundice, provided the prothrombin values are very low, may be obtained only after all symptoms of the disease have disappeared. Existence of a severe hepatocellular icterus is suggested when prolonged prothrombin time is not restored to normal by one to three vitamin K injections (30 mg for each of them). Low prothrombin levels were not demonstrated in all of the cases with partial obstruction of the common bile duct. In obstruction by stones associated with cholangitis the prolonged prothrombin time can be restored to normal by methenamine injections, which result in liberation of vitamin K following the destruction of colon bacilli. In cases with cardiac decompensation and enlarged liver low prothrombin values are found which were spontaneously increased with restitution of compensation. Failure to restore compensation by administration of vitamin K may signify the presence of a beginning cirrhosis. A true picture of the prothrombin amount is revealed on determination of the prothrombin curve. That is particularly demonstrated in chronic hepatocellular icterus. Prothrombin values below 20 per cent are not always associated with spontaneous hemorrhages. These may be caused not only by lack of prothrombin but also by the increased permeability of capillaries. The prothrombin time was demonstrated to be normal in cases of symptomatic hemophilia and in all cases of hemorrhagic diathesis with the exception of 1 case of thrombopenic purpura. The shortest prothrombin time was found in a case of hemophilia. The prognostic value of the vitamin K test in liver disease is emphasized. Recovery occurred in all cases with normal prothrombin time and in cases in which prothrombin time was readily restored to normal by vitamin K administration. Yellow atrophy of the liver was suspected in a case with a low prothrombin level. Clinical signs of the condition became manifest somewhat later.

Parathyroprival Tetany—Lamelas and his collaborators review the etiology and pathogenesis of parathyroprival tetany and report 2 cases which occurred among 87 persons operated on for goiter. The incidence of postoperative tetany is reported by other surgeons, varies between 0.5 and 3.4 per cent. The authors evaluate treatment with parathyroid injection and dihydrotachysterol, with vitamin D in the form of calciferol and with calcium. In mild cases a lactovegetarian diet is sufficient, in severe cases and during attack parathyroid injection or dihydrotachysterol should be employed.

Book Notices

Stuttering: Significant Theories and Therapies By Eugene F. Hahn. Foreword by Sara Stinchfield Hawn. Cloth. Price \$2.15. Pp. 177. Stanford University Press. London: Oxford University Press, 1941.

This is an important book. The author has achieved a number of desirable ends in his compilation of the various theories of and therapies for stuttering. He has selected almost all the authorities in the field of speech pathology, including eight from abroad and to assure the complete accuracy of his data he has had them either write their own digests of their respective points of view or edit the digests which he prepared. It is not within the province of a reviewer to go into the merits of the different theories and therapies discussed. However, a few examples of the diverse procedures employed in treating stutterers—loud sighs, release of the adduction action of the vocal cords, thought training, exercises 'breath chewing', psychoanalysis, building up visualization, building up a one word dominance, voluntary stuttering, requiring 'skill in controlling the form and duration of the stuttering reaction'—influencing the disturbed metabolic mechanism of the stutterer—will give the reader some idea of the confusion which exists in the field. The twenty-five digests are clearly and concisely written and in toto, present an excellent summary of all the important theories on stuttering. An appendix and an index complete the book. In the appendix the author stresses the advisability of employing a variety of therapeutic measures in the treatment of the stutterer and gives in detail a number of clinical procedures which he and others have found useful. Thus the book offers much valuable material to the teacher or clinician who wishes to correlate theory and practice. This volume should be required background reading for all who are interested in the stutterer's problem. In fact, the authorities whose theories are presented in the book should have it on their must list. Comparative study is an important step toward clarification.

These Mysterious Rays: A Nontechnical Discussion of the Uses of X Rays and Radium Chiefly in Medicine By Alan J. Hart, M.D., M.Sc. (Med.). Cloth. Price \$2.75. Pp. 218 with 28 illustrations. New York & London: Harper & Brothers, 1943.

No doubt many radiologists have wished they might write a popular book on x-rays which would be acceptable to the medical profession and provide attractive reading for the public. The author has succeeded enviably well in combining skill in writing with a vision born of long experience to produce a highly readable and dependable book on radiology for popular consumption. It sets forth important facts regarding diagnostic and therapeutic radiology in nearly nontechnical language. The author has succeeded in taking much of the mystery out of the topic by the use of a clever conversational style. There is a general discussion on the employment of the x-rays and radium in medicine and a general review of the problem of cancer, the use of ultraviolet radiation and the application of x-rays and radium in industry and certain medicolegal topics. Practical advice is given concerning cancer quacks and commercial x-ray laboratories. The author has done radiology a great service in providing this convenient and useful volume. It would be a valuable and popular addition to the literature on the waiting room table in any radiologist's office.

Medical Parasitology: A Laboratory Manual By I. Jacques Letwin, B.Sc., M.S., M.D., Associate Professor of Parasitology, Middlesex University School of Medicine, Waltham, Mass. Third edition. Paper. Pp. 130 with 62 illustrations. Waltham, Mass.: The Author, 1944.

This loose leaf booklet is printed as a guide to a twenty hour course in parasitology for medical students. Numerous blank pages are interspersed for lecture and laboratory notes. Sixty-two illustrations accompany the directions for laboratory exercises. Morphologic details and parasites of little or no medical importance receive undue emphasis. Instead greater stress could well have been given to the life cycles and methods of diagnosis of the important parasites. It is unlikely that this manual will be of much value to any students other than those taking the particular course for which the directions were written.

A Workbook of Elementary Pharmacology and Therapeutics (Including Drugs and Solutions) By Luella C. Smith, R.N., B.S., Instructor in Science, Methodist Hospital, Indianapolis. Second edition. Paper. Price \$2. Pp. 700. St. Louis: C.V. Mosby Company, 1943.

This embryonic manual gives a sad impression of grade and high school education. That so much drill in simple arithmetic is needed is a sad commentary. The book has 300 pages, of which 184 are occupied with such diversions as changing $\frac{3}{4}$ to percentage or answering "How much 10 per cent sodium bicarbonate is needed to make a quart of 5 per cent?" Ignorance of simple arithmetic has been found also in pharmacy, in dentistry and in medicine. Yet the demands for entrance would qualify for a university president. Since the book deals with remedies and their administration, one may wonder why there is no suggestion of how to stimulate better scholarship in the grade and high school, such as the elimination of coddling devices and the introduction of means of promoting toil, sweat and study.

Teachers in all schools are aware of the deficiencies in the students, and to give credit where due we think that the training, though quite deficient, is better than in the past and is improving. The author recognizes the student's deficiency and instead of useless fault finding sets out to correct it.

The book is divided into thirty-eight chapters or exercises, very elementary, yet important. Addition, subtraction, simple fractions, multiplication, division, improper fractions and similar grade school work is reviewed. More pertinent is the work on weights and measures, and the relationship of the metric and apothecary systems.

Because some doctors write prescriptions in Latin, she gives a list of abbreviations and their meaning but the connection between the abbreviation and the Latin words is a void, and the whole devoid of anything educational.

Medical men are to blame for much of this nonsense. And strange to say, medical men who best know Latin use it least. They have the good sense to keep dark the fact that if they are Latin scholars it usually is at the expense of less knowledge of medicine and pharmacology.

The greatest service of this work book is in illustrating defects in our whole system of education. The author sees students as they are, not as their qualifications state. Recognizing their deficiencies, she applies the treatment that is indicated. Students who are deficient in simple arithmetic are not likely to benefit from lectures on the pH of solutions or in logarithmic variations.

Under the present conditions this quite elementary book may be used as a review by students in the basic medical sciences. One or two weeks might be spent on it as a review, with profit. If more time is needed, the students are hopelessly incurable.

The content of Pharmacology and Therapeutics is too meager to deserve the title. The U.S.P., N.F., N.N.R. and Useful Drugs are given as references.

Communicable Diseases for Nurses By Albert C. Bowler, A.B., M.S., M.D., Head of the Department of Communicable Diseases and Clinical Professor of Medicine, University of Southern California, Los Angeles, and Edith B. Pillant, R.N., Director of Nursing, Los Angeles County Hospital, with the assistance of Wilton L. Halverson, M.D., D.P.H., State Director of Public Health for California. Fifth edition. Cloth. Price \$3. Pp. 792 with 83 illustrations. Philadelphia & London: W.B. Saunders Company, 1943.

Although the book is intended primarily for the nurse its scope should make it useful also for the medical student and practicing physician. Nursing procedures are given in detail and all the common communicable diseases are presented concisely with references at the close of each chapter. Many additional infections less often encountered in this country but now of special interest because of war conditions receive attention. There are chapters concerning yellow fever, malaria, dengue, plague, cholera and typhus. Of the total fifty-seven chapters, fifty-one relate to different diseases. Among the others is an excellent discussion of the sulfonamides in this edition. Numerous illustrations and fever charts are of added value and a glossary of medical terms will be convenient for the student. Any one interested in communicable diseases will appreciate the authors' work and the manner in which it is presented by the publishers.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY CONSULTING THE AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES. THE EDITOR'S OFFICE IS THE ONLY ONE TO BE OF VALUE IN KEEPING DOWN THE BACTERIAL CONTENT OF AIR, IS IT LIKELY THAT ITS USE IN CIGARET TOBACCO MIGHT BE SIMILARLY EFFECTIVE IN THE UPPER RESPIRATORY TRACT?

PROPYLENE GLYCOL NOT BACTERICIDAL IN CIGARET SMOKE

ANSWER—The vaporization of propylene or any other glycol in a burning cigaret would have no effect on bacteria in the respiratory tract for the reason that propylene glycol is not bactericidal in dilutions of less than approximately 50 per cent. The reason propylene glycol vapor is bactericidal in such minute concentrations in the air is that the molecules of the glycol striking the small bacteria-containing droplet quickly build up a concentration of glycol within the droplet of 50 to 80 per cent. To produce such a concentration of propylene glycol in the fluid on the surface of the respiratory mucosa would require a relatively enormous amount of glycol—much more than could be inhaled even by breathing a fog of this substance.

HEADACHES ASSOCIATED WITH PREGNANCY AND ENDOCRINE THERAPY

To the Editor—A white married woman aged 32 has complained of frequent headaches for the past ten years. These attacks have had no definite association with the menstrual flow as to the time of their occurrence. The sinuses were found to be involved at one time, but she shows no disease of present that can be demonstrated by x-ray or physical examination. There has been slight hypotension and a basal metabolic rate of minus 10 has been obtained on two occasions. During two pregnancies there has been complete relief from headache after the third to fourth month. These did not return until a month or so following delivery in each instance. This suggested the possibility that relief might be obtained by the use of endocrine therapy, but I have been somewhat uncertain which would be the best preparation to employ. Fairly immediate relief of the individual attacks is obtained by the use of small injections of ergotamine tartrate.

Major, M C, A U S

ANSWER—The fact that an illness is relieved during pregnancy does not necessarily imply that endocrine preparations will relieve the illness during the nonpregnant state. During gestation there is a pronounced and progressive increase in the amount of estrogen in the circulating blood and in the urine throughout the entire ten months. In addition there is a precipitous increase in the amount of gonadotropic hormone during the first two months of pregnancy, a gradual drop during mid-pregnancy and then another moderate increase toward the end of pregnancy. The available commercial preparations of pituitary are in general unsatisfactory. Of the estrogens there are many excellent and potent products. However the administration of even large amounts of estrogen has failed to relieve women of ailments which spontaneously remain in abeyance during pregnancy. Such therapy has been tried for women afflicted with migraine, asthma and other conditions which were troublesome in the nonpregnant state but absent during gestation. Unfortunately the results have not been satisfactory.

A diametrically opposite type of treatment has also been tried. Some women with migraine who were free of the affliction during one or more pregnancies have been castrated by roentgen therapy in the hope that elimination of ovarian function would cure the migraine. The results have been disappointing.

TACHYCARDIA, TUBERCULOSIS AND ALTITUDE

To the Editor—A man aged 32 with moderately advanced bilateral pulmonary tuberculosis has been at complete bed rest for the past two years. His pulse on waking is 78-84, it regularly increases to 102-106 during the day, and if he sits up in bed in the evening it goes to 116-120. A few extra systoles are present but no murmurs or cardiac enlargement, the red count is 5,600,000, white count 8,000, hemoglobin 103 per cent, blood pressure 118/85, maximum daily temperature 99.6 F. According to a tuberculosis specialist his tuberculosis is "insufficient to account for the tachycardia and may be due to a slight degree of hyperthyroidism." Blood cholesterol is normal. The patient desires to continue his treatment in Colorado or New Mexico and wishes to live in one of three towns situated at 4,900, 5,900 or 6,400 feet altitude. To reach the first would necessitate passing through (by train) elevations as great as 8,000 feet. His present altitude is 1,000 feet. Should his journey be broken to allow him to adjust to the increasing elevation and if so how often and for how long should each stopover be?

M D, Oklahoma

ANSWER—Under the circumstances there need not be undue concern regarding the change of altitude. The patient may go direct to his destination. There will be no doubt a slight increase in the symptoms for a short while, but an adjustment will soon occur as it has with the thousands of other tuberculous patients who have made a similar change in altitude over the last fifty years. It would seem highly desirable that the diagnosis should be cleared before any move is made. Hyperthyroidism should be found if present. The same may be said with respect to severe cardiac or other common conditions.

The whole process, however, may be only tuberculosis. It is well to bear in mind that with all the facilities available one cannot see all tubercle-bearing tissue in the body and that sometimes small pulmonary lesions may be associated with extensive hilar lymph node and extrathoracic involvement. As long as symptoms are present the patient should receive treatment in anticipation of the healing of "occult" lesions even if the visible lesions have disappeared.

CORONARY HEART DISEASE IN PAINTER AND LEAD IN TISSUES

To the Editor—A white man aged 36 was suddenly seized with severe precordial distress. Physical examination did not reveal any abnormal findings. The pain was diffusely spread over the left side of the chest and was not helped by hypodermic morphine and papaverine. He died suddenly about four hours after the onset of the angina. At times when the pain was not so severe, his blood pressure was taken and was found to be 150/110 mm of mercury. Questioning was limited but it did reveal that he had been a painter for sixteen years and during the past few years had been troubled frequently by diffuse headaches. At autopsy a severe degree of atherosclerosis of the coronary vessels was found. At one point this sclerosis almost occluded the right coronary artery 1.5 cm from its origin. Microscopic study did not reveal any significant degeneration in the heart, kidneys, liver or brain. However, chemical analysis of the various organs for quantitative lead revealed the following values:

	Mg per 100 Gc
Liver	0.61
Vertebra	3.16
Brain	0.197
Blood	0.043
Intestinal contents	0.517

The problem which presents itself is to determine, if possible, the relationship between the increased amounts of lead present in his tissues, his occupation and the coronary sclerosis and coronary spasm. Did the post-mortem findings prove or disprove the question of occupational disease?

M D, New York

ANSWER—This man died probably as the result of a rather extensive degree of coronary heart disease. In all probability he would have had angina pectoris on effort before his death if he had exerted himself, quite likely he did have angina pectoris.

It is improbable that his occupation as a painter and the lead found in his various tissues had any direct relationship to his coronary heart disease. Only rarely indeed is a history of exposure to lead found in patients with angina pectoris and coronary heart disease even at his age, and it is uncommon for young painters to have angina pectoris. Lead does not actually predispose to arteriosclerosis. Dr Joseph Aub in his monograph on lead, pages 71 and 72, refers to a painter who was killed while at work by a fall and who showed much the same concentration of lead in his tissues: liver 0.68, skeleton 7.16, brain 0.22 mg per hundred cubic centimeters. He had always been well and there had been no symptoms.

Dr Aub has commented on the concentrations of lead in the case presented in this query. He thinks that the concentrations are not high enough to justify the diagnosis of active lead poisoning, being simply representative of a painter who has absorbed some lead.

SUDDEN DEATH AND ANESTHESIA

To the Editor—On page 1215 of The Journal of Aug 21, 1943, the statement is made that "acapnia or depletion of carbon dioxide can cause death only through the failure of breathing." On the contrary, such acapnia as is caused by irregular ether anesthesia as in the case under discussion is generally due to failure of the circulation. I demonstrated this in many papers in the American Journal of Physiology and some in The Journal which are summarized with full references in my book "Adventures in Respiration: Modes of Asphyxiation and Methods of Resuscitation," published by Williams & Wilkins Company, Baltimore, 1938.

If that patient had been treated with carbon dioxide and oxygen she would almost certainly be alive today.

DISORDERS AND LESIONS OF THE MALE URETHRA

OFFICE PROCEDURES

EDGAR G. BALLENGER, MD

HAROLD P. McDONALD, MD

ATLANTA, GA

AND

LIEUTENANT REESE C. COLEMAN

MEDICAL CORPS, UNITED STATES ARMY

Disorders of the male urethra are the cause of many disturbing symptoms. They are due chiefly to inflammatory conditions, obstructions and hyperemia or hyperesthesia. These disorders manifest themselves chiefly as abnormal discharges, urinary irritation and sexual disturbances. Inflammation and obstructions are intimately related. By this is meant localized inflammatory processes tending to produce fibrosis and obstructions in the areas so affected. It is equally true that obstructed areas in the urethra, whether congenital or acquired, tend to harbor infection. Each tends to perpetuate the other, inflammation produces fibrosis and obstructions, which in turn hinder the cure of infected areas. Considerable judgment is required at times, especially in chronic recurrent inflammation, to determine the correct plan of treatment. Formerly it was deemed inadvisable to dilate inflamed areas in the urethra even though an obstruction was known to be present and keeping up the inflammation, since the advent of sulfonamide compounds, however, with their remarkable germicidal qualities this view has undergone a decided change. The danger of bringing about the complications formerly feared by dilating obstructed areas no longer obtains, at least in those cases in which the infection is well controlled by one of the sulfonamide drugs. In consequence now the vicious circle often may be broken by dilating the obstructions which tend to keep up the infection. It naturally goes without saying that the instrumental dilation should be done with care and at first should be limited to the anterior urethra, furthermore, it should be carried out during the time in which the sulfonamide drug is being administered.

These rather radical views would not be advised had we not been impressed repeatedly with the manner in which urethral infections disappear when treated simultaneously with the dilation of obstructions and the administration of sulfonamide drugs.

GONORRHEA

It is recognized that many urologists do not treat venereal diseases. The treatment of gonorrhea, however, is an office procedure which merits careful consideration of those who do treat it.

In the treatment of gonorrhea we recognize three groups: (1) those in whom the discharge has not been present for more than forty-eight hours, (2) those in whom the discharge has been present for more than forty-eight hours, (3) those in whom the discharge is chronic or recurrent and perhaps with complications.

Acute Gonorrhea, When the Discharge Has Been Present for Less Than Forty-Eight Hours—If the infection is of recent origin with the usual incubation period, and if the discharge has not been present for more than two days, a high percentage of prompt cures may be obtained by the combined use of sulfathiazole orally and a 5 per cent solution of mild protein silver sealed in the anterior urethra once a day for four days. The sulfathiazole should be administered in doses of 1.5 Gm each, four times a day for the first two days, then 1 Gm four times daily for the next two days. The 5 per cent solution of mild protein silver should be freshly prepared each day. The patient urinates, the meatus is washed, and 1.5 cc of the solution is injected into the urethra and retained with clamps. Collodion is applied with a camel's hair brush to the meatus and surrounding glans penis. The most satisfactory clamps are those used in laboratories for holding test tubes. When the collodion has dried, the clamps are removed. A condom is then placed over the penis and the patient is instructed to postpone urinating for four hours if possible. Straining efforts which might cause the solution to escape should be avoided. U S P collodion (nonflexible) should be used. The treatment is administered once a day for four days. During this time the sulfathiazole is continued as described.

All treatment is discontinued after the fourth day. Careful observation is then begun. If there is no return of discharge within a week the patient is permitted to make a test with alcoholic beverages if he so desires. If, for another week, no discharge appears, a urethral sound is introduced as a further provocative test. If this procedure does not cause a return of discharge or cloudiness of the first glass of urine treatment is still omitted but the patient is observed from time to time for four weeks longer, during which additional sounds are introduced into the urethra. If at the end of this time there is no discharge and the urine is clear the patient is told that he is well. So far we have not seen a recurrence when these tests were negative.

Let us again emphasize the fact that this plan of treatment is not employed for patients whose discharge has

been present for more than forty-eight hours or when the incubation period was not within the normal limits.

The prospect for a prompt cure is less favorable when gonitis has occurred during the incubation period or when urethral strictures are present.

When the Discharge Has Been Present for More Than Forty-Eight Hours.—Under these circumstances the chances are about 80 to 90 per cent that a cure may be effected within two weeks or less by sulfathiazole. Thus, of course, implies that the patient can tolerate the sulfonamide drug in doses of 1 Gm. three or four times a day, preferably after meals and after a glass of milk at bedtime. For those who cannot take the recommended dose of sulfathiazole the amount may be reduced and yet may be effective. Here supplementary measures such as the usual urethral irrigations and injections should be employed. In spite of such routine care there will be a percentage of failures which require additional measures. What these shall be naturally depends on the extent of the failure and its most likely cause or causes. If it seems that the gonococcus appears to be of the resistant type, a change to sulfadiazine or to sulpyridine may at times be of value. If these are not effective in controlling the infection mild routine measures should be patiently used until it seems safe to ascertain whether or not there is an obstruction or a pocketed area in the anterior urethra acting as a retarding factor. Of course such instrumentation should never be undertaken when there is a complication such as coarctitis, proctitis, seminal vesiculitis or epididymitis.

Chronic or Recurrent Gonorrhea.—This requires unhurried efforts to ascertain the factors which retard the elimination of the infection.

Probably the commonest causes of failure to obtain reasonable satisfactory cures with sulfathiazole are stopping the drug too soon and pocketed infection in the glands of Littre or at urethral strictures.

Prognosis.—The time required to cure a patient with acute gonorrhea varies with (a) the promptness with which treatment is started, (b) the type of treatment employed and (c) the response to treatment.

The quickest cures are obtained with the combined use of sulfathiazole and mild protein silver sealed in the anterior urethra. This plan should be employed only when the patient reports for treatment within two days after the urethral discharge appears. After the infection has become well established, uncertainties as to the time for eradication are increased. They concern the tolerance of sulfathiazole, urethral strictures, the development of complications, the existence of pocketed areas in which the micro-organisms may have become entrenched and to drug resisting qualities developed by the gonococci.

The danger of infection being carried to the eyes by accidental transference is slight, but patients should be warned of the possibility and urged to exercise care in preventing such infection. Complications such as epididymitis and prostatitis are much less frequently seen in patients who are treated with sulfonamide drugs than in those who do not or cannot take them. Dosage at four hour intervals is recommended, as the blood concentration is kept more constant thereby.

Ambulatory patients who are taking sulfonamide drugs should be warned of the possibility of nausea and dizziness. Particularly should this be called to the

attention of airplane pilots, railway engineers, bus drivers and persons similarly employed. Drug fever is seen occasionally, it promptly disappears with the omission of the drug and forcing of fluids. Skin rashes are not uncommon and may take many forms. Acute agranulocytosis and hemolytic anemia are rare, when suspected blood counts and hemoglobin determinations should be made promptly and the drug discontinued if a definite decrease of red or white cells is noted.

NONSPECIFIC URETHRITIS

In the great majority of cases nonspecific urethritis is due to an obstruction at the meatus or in the urethra or to infection in pocketed areas such as in the glands of Littre or Cowper's gland, the prostate or the seminal vesicle. A small meatus or a stricture of the urethra tends to cause extension of infection into pocketed areas or "dugouts" from which its eradication requires a higher degree of immunity or a greater germicidal effect from medical measures than is required if the infection is limited to smooth mucosa.

For many years our most satisfactory treatment of nonspecific urethritis has been by meatotomy, when the meatus is small and by the dilation of strictures when they are present. No longer are astringent injections or irrigations employed. More prompt and more lasting benefit is obtained by establishing a normal caliber of the urethra and less frequently by electrical coagulation of infected glands of Littre. Of course attention is given to the prostate and seminal vesicles when needed. Endoscopic treatments are not used except when the other measures have failed, they usually are needed only when the glands of Littre harbor gonococci. In addition to these measures sulfonamide drugs, preferably sulfathiazole, are simultaneously employed.

Poor kidney function and obstructive lesions of the urinary tract are contraindications to the administration of large doses of sulfonamide drugs. If such lesions are suspected, or if large dosage is contemplated renal functional tests should precede the administration of sulfathiazole.

MEATOTOMY

Adequate diagnosis and treatment of urethral disorders is not feasible through a small urethral meatus. By a small meatus is meant one which will not admit a 26 F. bulb. In such cases meatotomy is necessary for diagnosis as well as for treatment of the usual urethral disorders such as chronic recurrent urethritis, deep urethral irritation and strictures.

Enlargement of the urethral meatus is accomplished with little discomfort by incision after the injection of 1 per cent solution of procaine hydrochloride into the tissue between the meatus and the frenum. After the meatus is incised to 30 F., as indicated by a bulbous bougie the urethra should be tested for strictures by the introduction of bulbs. A sound one size smaller than the largest bulbous bougie which would pass through the anterior urethra is then introduced through the deep urethra. The sound is removed, and to the incised area at the meatus Monsell's solution is applied with a cotton swab. This stops bleeding and lessens the discomfort when the urine is voided. The patient is instructed to introduce a glass rod such as is attached to the stopper of germicidal solutions, about $\frac{1}{2}$ or $\frac{3}{4}$ inch into the urethra and press downward to prevent the cut surfaces from growing together. This

procedure is carried out by the patient every night for about ten days until the mucosa has covered the incised surface. Meatotomy thus carried out affords excellent results.

URETHRAL STRICTURES

Strictures of the urethra, bottle necks in this urinary passageway, are of common occurrence. They may be congenital, acquired or both. The scope of this paper does not permit a discussion of the various types of strictures or of the details of the inflammatory changes and chemical or traumatic injuries which produce the required fibrotic narrowing of the urethra. It seems more desirable to discuss the ill defined symptoms and management of strictures amenable to office treatment.

The recognition of a narrow point in the urethra is so easy and so important that even the most casual examination, unless the urethra is acutely or subacutely inflamed, should include the introduction of bulbous bougies into the anterior urethra. In no other manner can it be known that the urethra is normal in caliber. Sounds are not of value in the diagnosis of urethral strictures, and the symptoms may be wholly misleading. Obstructions of fairly large caliber may be associated with and causing a chronic "gleety" discharge which will not clear up until after the stricture has been dilated. The same may be said of low backache and of postpubic or pelvic discomfort. Itching along the urethra or in the perineum results more frequently from urethral strictures than from all the other causes. Frequency in micturition, "nervousness" and sexual disturbances are not uncommon symptoms of urethral strictures. The rather surprising thing about all these vague symptoms of urethral strictures is that they do not vary in proportion to the narrowness of the stricture.

While strictures of medium and large caliber may be attended by a chronic or recurrent urethral discharge, strictures of small caliber may not cause any abnormal secretion. Retention of urine, partial or complete, after exposure to cold, sexual excess, alcoholic excess or voluntary retention beyond the usual time may result from strictures of fairly large caliber.

Periurethral abscess, fistula and urinary extravasation may arise from neglect of strictures or from false passages produced by instrumentation.

Following transurethral resections of the prostate strictures of the urethra which previously had given little trouble are quite likely to require dilation. This should be started about ten days after the resection.

The treatment of strictures should always begin with a meatotomy when the meatus will not admit a 26 F bulb.

Gradual Dilation of Urethral Strictures—Treatment by gradual dilation is the method of choice in the management of urethral strictures. The dilation should be so gradual that at no treatment is the trauma sufficient to require repair by scar tissue. Dilation with sounds is safer than with the Kollmann dilator. Gentleness and care in the passage of urethral sounds are of prime importance. The hurried passage of a sound increases both pain and the likelihood of making false passages. For patients who are unusually nervous or whose urethras are very sensitive, anesthetic jelly injected into the urethra and gently pressed into its deeper part reduces decidedly the pain caused by

urethral instrumentation. After the injection of the anesthetic jelly a clamp is placed near the meatus and the jelly allowed to remain in the urethra for about five minutes. K-Y jelly is then injected into the urethra and the sound slowly passed. If the stricture will not admit a 22 F sound it is preferable to use a Phillips tapering bougie. If this cannot be passed, an effort should be made to introduce a filiform, woven or whalebone. What plan to follow in case success attends this procedure depends on the difficulty experienced and on whether or not the urethra is sufficiently dilated to permit voiding urine. If one is in doubt, the filiform may be tied in the urethra, where it may be allowed to remain for several days. Patients nearly always void satisfactorily around such retained filiforms. Subsequent dilations are likely to be easy if no false passages are made. Whether hospitalization of the patient and an operative procedure should be carried out must be determined by a consideration of the patient's general condition and by local complications such as fistulous tracts or abscesses.

DISORDERS OF THE DEEP URETHRA

Acute inflammation of the deep urethra is readily recognized by the painful symptoms referable to this area, frequency in voiding and pus in the last part of the urine. In such inflammation the prostate gland inevitably also is involved. Sulfonamide drugs now control infection of this part of the urethra most of the time so well that little more than these drugs, hot baths and palliative measures are required. Attention to the prostate, however, is indispensable in the management of inflammation of this area.

It is mainly with chronic disorders of the deep urethra that this discussion will deal. Here is the meeting point of the urinary and sexual tracts in the male. It is not surprising, therefore, to find in this region disorders causing bed wetting in childhood, masturbation in youth, inflammatory processes and sexual disturbances in adult life and urinary obstruction in old age.

Among the lesions commonly seen in the prostatic urethra are papillomas, cysts, bullous edema, diverticula, false passages, varicose veins, angiomas, bands, bars, valves, fibrous contractions, urethritis and other abnormalities of the verumontanum, elongation or distortion produced by hypertrophy of the prostate gland and abnormalities which result from transurethral resection of vesical neck obstructions.

These lesions are readily recognized when seen through the McCarthy panendoscope. Hyperemia and hypersensitive conditions, which are the commonest of the deep urethral disorders, are readily detected by the passage of urethral sounds. Nearly all sexual disturbances arise from endocrine deficiencies and from lesions of the verumontanum while practically all obstructions are found back of it.

Failure to recognize the disorders of this vulnerable part of man's anatomy is due largely to failure to suspect them as being associated with the more or less ill defined symptoms produced.

Hyperemia and hyperesthesia of the deep urethra respond so well to treatment with sounds and instillations of 1 or 2 per cent solution of silver nitrate that more elaborate diagnostic measures than response to treatment are not required. If later this tentative diagnosis is shown to be inadequate urethroscopic studies

may then be made with less discomfort than if preliminary dilation with sounds and instillations had not been employed.

The cutting current is generally used for correcting gross lesions of the deep urethra, congenital or acquired such as valves, bars, bands and fibrous contractions. The coagulation current is used for small papillomas, cysts and varicosities.

The Verumontanum—As the verumontanum is a very sensitive part of the prostatic urethra and is pressed on by muscular contractions of this area disturbances of the verumontanum result in a variety of urinary and sexual symptoms. Unless suspected as the cause of these symptoms the sensitive verumontanum may not be regarded as their cause. The anatomic position of the verumontanum made it inaccessible for observation with the ordinary cystoscope and it was not until the advent of the close vision cystourethroscope that accurate observation and studies of this area were made. Even today lesions of the verumontanum and the utricle are recognized less frequently by urologists than are the common bladder and renal disorders.

The pathologic changes most frequently noted are hyperemia, hyperesthesia, adhesions, cysts, neoplasms and strictures of the ejaculatory ducts. Associated with some disorders of the verumontanum are urethral obstructions and chronic prostatitis.

The symptoms of disorders of the verumontanum are postpubic or deep perineal itching, discomfort or pain, urinary frequency, nervousness or sexual symptoms such as premature emissions or impotence. Enuresis and excessive or prolonged masturbation in boys should suggest the possibility of an abnormal condition of the deep urethra or verumontanum as a causative factor. Occasionally persistent infection may result from infection in the utricle.

The most common condition caused by abnormalities of the verumontanum is sexual "neurosis" or sexual "neurasthenia." This is often associated with a mental disturbance or "nervousness" all out of proportion to the pathologic process causing it. And we say "causing it" advisedly for the reason that the symptoms disappear almost directly in proportion to the correction of the abnormalities of the verumontanum.

Unfortunately disorders in the prostatic urethra are not characterized by lesions always discernible by cystourethroscopic study. They are made just as obvious, however, by appropriate remedial measures. The cure of the multitude of ill defined complaints is quite as convincing as urethroscopic studies could be. By this is not meant that adequate studies should not be made but rather that, at times, and not infrequently, appropriate treatment with sounds and medication to the prostatic urethra will correct symptoms not assignable to any lesion sufficiently gross to recognize endoscopically.

Appropriate treatment of hyperemia and hyperesthesia of the verumontanum consists in correction of etiologic factors such as prolonged "necking" without sexual gratification, masturbation, withdrawal before emission and other such abnormal habits.

The urethra should also receive corrective treatment for abnormalities such as a small meatus and stricture if present. Even though no stricture is found, sounds should be introduced about once a week and allowed to remain in the urethra for about ten minutes. These tend to lessen the deep urethral hyperesthesia and

hyperemia and are of value whether or not urethral strictures are present. In three or four weeks the sound should be followed by an instillation of 2 cc of 1 per cent silver nitrate. In subsequent treatments the strength of the instillation should be increased gradually to about 2 per cent.

After tolerance to these treatments has been acquired and if symptoms still persist, cystourethroscopy should be made at which time adhesive bands, cysts or polypoid growths should be corrected by the high frequency fulgurating current or with cystoscopic scissors. This is not the procedure to be employed for hyperemia or hyperesthesia of the verumontanum. Instead at a later treatment silver nitrate in a concentrated form is applied directly to the verumontanum through an endoscope. This is not done until tolerance of the deep urethra to instrumentation has been obtained by the introduction of sounds and by the instillations of silver nitrate. Application of concentrated silver nitrate (20 per cent) is facilitated by the use of an endoscope with rounded edges not requiring an obturator. Observation is thus permitted as the endoscope is introduced. When the verumontanum comes into view the applications may be made without undue fumbling or trauma. For many years we have found that the discomfort incident to the application of concentrated silver nitrate to the verumontanum and deep urethra is greatly lessened by first applying a 50 per cent solution of phenol. This application is followed by a dry applicator and then the application of silver nitrate is made. When preceded by suitable preparatory treatments these applications are rendered comparatively free from pain, both immediate and late. They are likely to be followed by frequency in voiding for three to twelve hours and occasionally by terminal hematuria. These mildly disturbing reactions however are unimportant when compared to the benefit derived from the treatments. It is our impression that the applications of silver nitrate to the verumontanum is decidedly preferable to coagulation of this area with the high frequency current.

Let it again be emphasized that these applications should not be employed until after tolerance to deep urethral instrumentation has been induced by sounds and instillations of 1 and 2 per cent solutions of silver nitrate.

Vesical Neck Contracture—Following transurethral resection, contracture of the vesical neck has been observed not infrequently. This obstruction is in the form of an iris diaphragm-like fibrous ring at the internal urethral opening. Patients with this condition have symptoms of deep urethral irritation and slowing down of the stream after an apparent excellent immediate result. This diaphragm-like contraction is of fibrous tissue and is more likely to occur in patients following resection of small fibrous prostates than in those with adenomatous obstructions, also when the resection is carried too deeply in the floor at the region of the internal sphincter. For many years it has been our practice to do cystourethroscopies after transurethral resections. These examinations are made from two to four months after the resection. When fibrous contractures are observed we customarily use cystoscopic scissors to incise this fibrous tissue. Little pain is occasioned by this procedure and relief usually is immediate. Weekly dilation of the posterior urethra

with the Kollmann dilator is employed to prevent the recurrence of the contraction as healing takes place.

Mild incontinence has been noted occasionally following transurethral resection. This condition varies from a slight weakness of the external sphincter which allows a few drops of urine to leak when straining or coughing to a real incontinence. Examination through the panendoscope reveals damage to the sphincter usually in the form of a small cavity or area of destruction on one side of and slightly anterior to the verumontanum. Light fulguration with the high frequency current directly over this area causes fibrous tissue formation which contracts the gap in the sphincter muscle and improves continence. Additional light fulguration at five to six week intervals may be needed to bring about complete continence. These treatments are usually carried out in the office since only light fulguration is needed.

BACKACHE

Low backache in the male responds remarkably well to urethral dilation and massage of the prostate gland. Just why such results should occur we cannot say. Strange as it may seem, relief of low backache and pelvic discomfort often follows prostatic massage and the introduction of sounds even when the prostatic secretion shows few or no pus cells and strictures of the urethra are not detectable. Among the patients with low backache who come to urologists, 50 per cent or more will respond to prostatic massage and the appropriate use of sounds and instillations of 2 cc of 1 or 2 per cent solution of silver nitrate into the deep urethra.

ENURESIS

Unless bed wetting is caused by some definite condition such as a cord lesion, vesical neck obstruction with residual urine or from a stone in the bladder the most dependable treatment is dilation of the urethra with sounds or bougies. As with adults, meatotomy should be done when the meatus is small. This plan of treatment is employed both for boys and for girls. The dilations are administered once a week and are usually the only treatment needed. The bed wetting usually stops after from one to ten treatments.

Occasionally in boys instillations of 1 or 2 per cent solutions of silver nitrate into the deep urethra after each treatment with the sound will be required. In boys 1 or 2 per cent solution of Intracaine is injected into the urethra before the sounds are introduced. This does not completely relieve the discomfort, but with gentleness, a few pennies and 'Popeye or football talk' the treatments nearly always may be carried out satisfactorily.

SUMMARY

Chronic urethral inflammations and irritations are most frequently associated with causative obstructions. Success in treatment often depends on the treatment of the inflammation simultaneously with dilation of strictures.

Disorders and lesions of the deep urethra are the cause of many of man's ill defined and disturbing complaints, especially those which concern pelvic discomfort, urinary symptoms and sexual impotence.

When employed with reasonable judgment and a fair degree of skill treatment of lesions of the prostatic urethra usually respond satisfactorily.

DYSURIA AND NOCTURIA IN THE PRESENCE OF NORMAL URINE IN THE FEMALE

G. F. McKIM, M.D.

P. G. SMITH, M.D.

AND

T. W. RUSH, M.D.

CINCINNATI

Recently we reviewed a series of 600 case histories in the female our object at that time being to evaluate all etiologic factors that were directly or indirectly responsible for bladder symptoms. We were impressed with the unusually large number of urethral caruncles and made them the subject of a special report recently published. Probably as a result of that publication we were asked to continue our studies of the remaining cases of that series and report our findings in only those cases in which, although bladder symptoms were present there was an absence of pyuria. To conform with this request we rechecked the histories of that series and eliminated 86 cases in which upper urinary tract involvement and obvious bladder disease such as tumors and stones were the basic etiologic factors in the production of bladder symptoms. This left 312 cases, in 160 of which pyuria and urinary tract infection were present and in 152 infection was absent. The latter group will be the subject of this report. We will briefly discuss some of the more common lesions found to be the causative factors in the production of bladder symptoms and will discuss in detail our methods of examination and refer briefly to therapeutic measures.

This review brought out two points of interest with which we are certain all urologists will agree. First there is an apparent lack of interest shown in these bladder cases by the medical profession. Treatment is too often on a "pay as you go plan," and seldom is there any attempt at a local or physical examination. Second, when these patients after many years of suffering consult a urologist they expect him to have the knowledge also of the following specialists: dentist, gynecologist, internist, laryngologist, neurologist, orthopedist and proctologist.

We must face the cold fact that these patients come to us for relief. They are suffering with 'sick bladders' and usually have been either inadequately, excessively or unnecessarily treated. It is our duty, not only to give them the benefit of our experience as urologists but to utilize our full knowledge of all specialties. We must not turn them away as being neurotic until that diagnosis is definitely established.

We try to impress on our medical students the necessity of obtaining an accurate history of all previous ailments with special reference to all bladder symptoms, previous operations (abdominal or pelvic), focal infections, menstrual cycles, personal habits such as food, drink and medication and even the type of cigarettes used. We must bear in mind during this inquiry that we are dealing with a strange individual in a strange environment, pessimistic as to our ability to give relief, nervous with anticipation of probable painful instrumentation and that foremost in her mind is the possibility that she may have a cancer.

METHOD OF EXAMINATION

When this patient has finished the story of her symptoms and if we have been alert many more pertinent facts can be elicited from her with some of the following interrogations: Do you have this frequency both day and night? Do you get any relief following urination? Is your pain before, during or after urination? Do you have 'loss of urine'? Is this loss more pronounced when you are on your feet or while in bed or noted more during exertion, coughing or sneezing? Are your bladder symptoms aggravated during your menstrual periods? Do you have local discomfort while walking or when sitting? The replies to these and other interrogations will frequently assist us in our examination. We cannot gain the confidence or cooperation of the patient unless we sincerely regard her as an ill, suffering human being.

Our routine method of examination is as follows. The patient is given to an intelligent, sympathetic nurse who places her flat on the x-ray examination table legs over the end, with her feet resting on a stool and her abdomen exposed. By this method we obtain satisfactory relaxation for palpation with special reference to localized or general pain or abnormalities; we can inspect for operative scars and if so desired can elevate or lower the table for general physical examination, including teeth, tonsils and x-rays. She is next placed in the lithotomy position and prepared for inspection of the external genitalia and urinary meatus. Urethral caruncles are one of the most frequent causes of symptoms, and in this position any of the various types located on the external urinary orifice can be easily identified. The examining physician must not be misled with a negative finding externally. It has been our experience that there are many caruncles located immediately behind a small caliber rigid meatus. In our series this "intraurethral" type is more prevalent than the external type and can easily be overlooked unless the following technique is used routinely. Insert in the meatus a small cotton swab saturated with a 10 per cent cocaine solution and allow it to remain five minutes. Then by gentle traction on the swab the intraurethral caruncle if present, can be pulled forward to the external orifice and its size, shape and location in the meatus can be noted. In several instances the contracted meatus necessitated dilation before the growth could be demonstrated on the inner surface of the urethral mucosa immediately behind the dilated orifice.

If a caruncle of either type is discovered regardless of its size or location, we rarely attempt further examination at this time unless we are dealing with an extremely cooperative patient. Hospitalization with proper environment is advised. We administer a light anesthetic, frequently low spinal so that a more satisfactory study of this tumor can be made. It is to be borne in mind that a urethral caruncle is a potential obstruction at the urinary outlet with the possible sequence of edema, stasis, infection of the urine and back pressure. With these sequelae as a possibility it is advisable that before any type of treatment is applied to the caruncle the patient should have the benefit of a complete study, not only of the urethra and bladder, but in most cases of the upper urinary tract as well.

RESULTS OF EXAMINATION

In our reported series of 202 cases of urethral caruncle the following findings in the urinary tract were noted:

Urethral strictures were present in 8 cases. The strictures were located immediately adjacent to the caruncles, and all these patients gave histories of previous applications of cauterizing solutions.

Urethritis was present in 81 cases, which showed varying degrees of easily recognizable urethral inflammation.

In 54 cases of cystitis at the vesical orifice cystic degeneration of the mucosa of the vesical orifice was easily demonstrated.

In 111 cases the bladder urine showed infection, both acute and chronic.

In 20 cases the bladder was contracted to a capacity of less than 6 ounces (178 cc).

In 2 cases interstitial cystitis was found and in 2 cases bilateral pyelonephritis.

As a result of the frequency with which involvement of the urinary tract above the caruncle was demonstrated in this series we conclude not only that urethral caruncles should be regarded as an important etiologic factor in the production of bladder symptoms but that in many cases they act as true obstructions to the urinary outflow and produce the complications of urinary obstruction.

In the routine of eliminating caruncles or other disease at the meatal orifice we have also noted abnormal changes of the labia and surrounding structures, including the anal orifice. There were 3 patients with uncontrolled advanced diabetes who showed edema and excoriations of the external labia. Although much valuable information can be obtained by a thorough inspection of the perineum in the multipara, the examination should include palpation of the rectovaginal partition with the gloved finger of one hand in the rectum and the examining finger of the other hand in the vagina. Frequently one can demonstrate perineal relaxations that visually have not been evident.

There were 5 cases in this series in which the bladder symptoms were the result of a partial procidentia caused by a relaxed perineum.

By separating the labia one can easily observe changes in the character of the mucous membrane of the lower vaginal wall, at the same time the presence or absence of any abnormal vaginal discharge can be detected. If such discharge is present microscopic examination is of course indicated. There were 5 cases in this series in which *Trichomonas vaginalis* was demonstrated and was the only causative factor in the production of bladder symptoms.

Pathologic change in and around the rectum should also be noted as it may be the sole cause of the production of bladder symptoms. Hemorrhoids have been commonly noted in our findings but in most cases have been disregarded, for we believe that they are usually the result of urinary straining and not the cause of urinary symptoms. There were 2 young women who came to us with very troublesome bladder symptoms in whom our examination was entirely negative except for the presence of hemorrhoids. Both of these obtained complete relief following appropriate treatment of the hemorrhoids.

External examination should be completed by a thorough and complete bimanual pelvic examination, and it is this portion of the examination which we believe to be of extreme importance. If not thoroughly satisfied with our findings we always request the assistance and advice of a gynecologist. This examination must determine the relative importance of relaxations of the anterior vaginal wall (cystoceles) and demonstrable abnormalities of the pelvic organs, either in size or in position, for the only manifestation of many of these conditions may be in the bladder symptoms they reflexly produce.

It is a fact acceptable to most urologists that the female urethra harbors numerous organisms, the so-called *fossa navicularis* being the chief offender. In view of that fact, one may be subjected to adverse criticism for passing a catheter through an infected urethra in order that a specimen of bladder urine may be obtained. We are certain that, if this procedure is carried out aseptically and without trauma and is preceded by proper cleansing of the external genitalia, no unfortunate results will follow. While all urologists recognize the extreme importance of having a catheterized specimen of urine for microscopic examination, its importance is seldom recognized by other members of the profession. In this series all patients were catheterized during our routine examination. We use graduated steel female catheters with aseptic technique, and our records show that we have no cause for regret in a single case.

Regarding this matter of acute inflammation, suppose we have a patient with a symptomatic bladder, pus, blood and organisms in the urine, and from those findings realize that we are dealing with an acute inflammation of the bladder of unknown cause. We are now faced with the question: Shall the investigation be continued with further instrumentation in this acutely inflamed bladder, or shall it be given temporary rest with internal medication, forced fluids, sedatives and so on?

TREATMENT

Bearing in mind surgical principles in treating inflammatory lesions in other organs of the body, our experience has been to let such a bladder alone temporarily unless an emergency condition demands further investigation. The patient's bladder is symptomatically ill, and she should be placed in a hospital, where she can be under supervision. Should circumstances not permit hospitalization, she is told that she has an inflammation of the bladder and we do not think it advisable to proceed further at this time.

Rest in bed is advised, at least 8 or 10 glasses of water in the twenty-four hour period, a soft diet, with special instructions to eliminate all fruit juices. The patient is given twenty-eight tablets of $7\frac{1}{2}$ grain (0.5 Gm.) sulfathiazole and instructed to take one tablet after meals and at bedtime. In prescribing this drug we tell her that it can be used for only a limited time and is not a cure but will probably relieve her acute symptoms. She is instructed to return at the end of one week. The majority of patients after following this plan of procedure return sufficiently improved to justify us in continuing the bladder investigation. For patients showing little or no improvement we immediately demand hospitalization.

Visualization of the interior of the bladder by cystoscopy was done in each of the 152 cases. Frequently a combination of two or more etiologic factors was found in the same case, such as pelvic abnormality and urethral cysts, or intramural cystitis. In the statistical portion of our report each condition will be discussed separately, and consequently some of these cases will appear in more than one group.

One of the common causes of bladder symptoms encountered in this series was cystic degeneration of the mucosa of the vesical orifice. This condition was noted in 70 cases. For the sake of simplicity and for want of a more appropriate term we will refer to this condition as "cysts." These cysts can be described as appearing in a variety of forms and may be classified as single or multiple, bullous or pedunculated. In several cases the two types were observed in the same individual.

The bullous type was encountered in 26 cases and appeared as superficial, rounded elevations beneath a thin urethral mucosa, which was more or less distorted by associated edema and congestion and resulted in the formation of folds of mucous membrane with intervening clefts. It is interesting to note that in 16 of these cases not only was the urine negative for infection but there was no residual urine. In the remaining 10 cases varying amounts of residual urine were found. The cystoscopic findings in the 44 cases in which the pedunculated type predominated presented an entirely different picture. In several patients the cysts were located inside the vesical orifice adjacent to the trigone and in others they were found in the urethra just outside the sphincter. Such cysts may be either single or multiple and appear to have a short pedicle and a uniform circumference and terminate in the form of a rounded knob protruding into the vesical orifice. They are covered with a very thin, colorless mucous membrane, and small vessels can be visualized coursing through their entire length from the mucosa to the apex. In none of the cases of the pedunculated type was there found to be residual urine.

Urinary symptoms varied in different individuals, though frequency was recorded in all, and in most cases, particularly those in which there was no residual urine, frequency was aggravated while the patient was on her feet. In the cases with varying amounts of residual urine there were the additional symptoms of burning, straining and occasionally hematuria. Three of the cases of the bullous type gave a history of urinary retention.

A personal experience during our examination of 1 of our earlier cases in this series is worthy of mention as it clearly proves the necessity of a thorough and complete examination in all cases of this type. The urinary history was suggestive of some type of bladder disturbance, but a catheterized specimen of urine was found to be negative chemically and microscopically. Following a careful examination including a very satisfactory visualization of the bladder, trigone and vesical orifice, no evidence of abnormalities was discovered. As the patient was very cooperative we introduced a urethroscope to the sphincteric margin and limited the inflow of fluid in order to visualize the vesical orifice before distention. Much to our surprise several pedunculated cysts were washed through the sphincter.

and were easily identified. We heartily recommend this procedure.

The cause of cysts at the vesical orifice has never been definitely proved. It may be purely coincidence, but a review of the 70 cases disclosed that there had been previous pelvic surgery in 48, and sufficient pathologic change was discovered in the remaining 22 cases to cause us to believe that any condition that will produce an alteration of the normal blood stream supplying the vesical orifice should be given consideration as an etiologic factor in the production of cystic degeneration of the mucosa of the vesical orifice.

In our early experience selected patients with these lesions were treated in the office. However, our most satisfactory and permanent results have been obtained when the patient was hospitalized. With light anesthesia, preferably low spinal, the lesions are treated by direct application under vision with the high frequency spark, it being necessary not only to cauterize the base of the protruding cyst but to cauterize gently all of the mucosa of the vesical orifice. We believe that this additional procedure not only will frequently prevent recurrences but will destroy certain cysts that are still submucoid in type and are not sufficiently far advanced to be visible during cystoscopy. It, of course, is advisable to refer the patient to a gynecologist for correction of any pelvic abnormalities. In our introductory remarks we suggested that the successful urologist is one who not only is qualified to practice his own rather limited specialty but is one who should be thoroughly familiar with the basic principles practiced in other related fields of medicine. We are prompted to emphasize these remarks after reviewing the findings in a series of 72 cases in which pelvic disease was demonstrated for most of the complaints so definitely directed our attention to the bladder that the possibility of fibroids and ovarian cysts being present was entirely overlooked. We cannot emphasize that fact too strongly.

It is far from our thoughts to trespass on the field of gynecology, but as urologists we must be prepared to make a satisfactory pelvic examination and as urologic teachers we should impress on our students the necessity of making such an examination in the cases of the type included in this series.

Each of these 72 patients complained of frequency of urination, especially severe during the day, following exertion and usually relieved by reclining. Burning and pain were also present in 50 of the cases. There was considerable difficulty in urination in 10 cases and retention in 6. When the bladder was distended in 35 cases it was noted that the normal contour was altered by filling defects, many of which were demonstrated with cystograms. Cystoscopy was accomplished in 3 cases with great difficulty and was not particularly satisfactory because of distortion of the urethra and bladder as the result of small impacted fibroids in the anterior surface of the uterine wall. Cysts of the bullous type were encountered at the vesical orifice in 10 cases and the normal contour of the trigone was definitely altered, both elevated and distorted, in 12 cases.

In several cases there was definite prominence of the veins of the bladder mucosa immediately inside the vesical orifice. These at times were so prominent as

to be true varicosities. All of this series of 72 patients were referred to gynecologists, who corrected the pelvic disease.

POSTOPERATIVE OBSERVATIONS

With the cooperation of the gynecologist we were fortunate in having the privilege of following many of these patients postoperatively, for many of them required rather careful postoperative care of the bladder.

All surgeons have their individual methods of handling postoperative bladder retention, and for many years we followed the custom of catheterization as indicated. Many patients developed bladder infections, so we altered that technique and now use the following procedure. The bladder is not disturbed after the operation until the patient complains of discomfort with an inability to void. In the meantime we use the hospital routine of all psychologic procedures, and if results are not obtained by these methods the patients are catheterized by an experienced nurse and the bladder is irrigated at the time with a weak solution of silver nitrate. Many patients become mentally perturbed because of this urinary complication, but they are assured that it is a common occurrence after surgery. After the initial catheterization we wait a reasonable length of time and if the patient is unable to void we introduce a number 18 French wing-tipped, self-retaining catheter permitting the urine to drain continuously in a sterile receptacle. The bladders are irrigated at least three times daily with 2 ounces (60 cc.) of sulfanilamide solution, sulfonamide drugs are given by mouth or intravenously as indicated. The catheter is removed on the third or fourth postoperative day. By this method we have obtained very satisfactory results.

We have been fortunate in being able to reexamine 10 of the aforementioned 12 patients within a year after surgery. The cystoscopic findings of all 10 showed that the trigone had returned to its normal condition, the varicosities had been obliterated in 8, but in 2 cases their appearance remained unchanged, though with improvement in bladder symptoms. From the 10 cases of recorded cysts the cystoscopic picture was unchanged, though the urinary symptoms were improved. Eight of these patients were later treated with very satisfactory urinary results. The 2 remaining patients refused treatment on the ground that the urinary results were satisfactory.

Pathologic examination in this series revealed 17 fibroids, 7 complete and 5 partial procidentias, 20 malpositions of the uterus, 3 unilateral ovarian cysts, 2 hypertrophied cervixes, 1 bilateral pyosalpinx, 2 calcifications of the uterus and 15 cystoceles with associated lesions.

The immediate postoperative results in the series were gratifying. Some of the patients returned in later years with what they thought was a recurrence of their original trouble, but examination proved the lesion to be inflammatory with an occasional bladder contracture. They obtained relief by routine office treatment, including bladder dilation.

COMMENT

In briefly commenting on this series, we feel that we can safely state that if any organ or organs in the female pelvis become deranged, either functionally

or pathologically, interfering with the normal bladder function, the bladder will signify this interference with a symptomatic response such as frequency, straining, burning or retention of urine.

In reviewing 23 cases of Hunter ulcers or interstitial cystitis as a primary cause of bladder symptoms we found that in all cases there was a history of chronicity with alternating periods of severe and mild symptoms with the fear that a cancer was present.

The cause is unknown but we have long been impressed with one factor namely that the urine of these patients practically always has a high pH . Possibly rather than a local condition of the bladder mucosa this pathologic change may be a local manifestation of some general metabolic irregularity.

In this series the symptom of frequency predominated and in most cases was associated with burning and suprapubic pain, but immediate relief of all symptoms was obtained after miction. We recorded clear urines in 18 cases pus and organisms in 5.

On cystoscopy, all these bladders had reduced capacities. The bladder mucosae showed a very mild congestion with either single or multiple areas of intense inflammatory reaction, and these areas were not confined to any special location and seldom to true, destructive ulceration. Overdistention of the bladder (irrespective of the capacity) is almost always followed by hematuria. All these cases were recorded in our early experience, and we followed treatment outlined at that time with only temporary results. In later cases not recorded in the series our best symptomatic results have been obtained with the use of solutions of silver nitrate in increasing strengths, depending on the patient's tolerance, and with gradual dilation of the bladder by the gravity method. We also give these patients large doses of acidifiers, as we believe that it is more than a coincidence that they respond to therapy much better when we are able to keep the urinary pH at a point lower than 6.

These patients must fully appreciate that while intramural cystitis is an extremely troublesome condition it does not place their lives in jeopardy. They must also thoroughly understand that the treatment is entirely symptomatic and that the severity of the symptoms may vary from time to time.

We have a group of 8 cases in another series in which the specific irritating effect of certain chemicals on the vesical neck has been amply demonstrated. This irritation is manifested by the bladder with the symptom of frequency of urination. Frequently the offending agent is one of the volatile oils, the port of entry being either by the lungs or by the gastrointestinal tract.

Several years ago we were confronted with a diagnostic problem by a woman whose only complaint was frequency of urination of several weeks' duration. As she described the symptom, it was more noted during the day. She presented ample medical evidence that eliminated all objective pathologic change. In summary, our detailed urologic findings were entirely negative and the urine was clear. In the meantime one of us discovered that she was an excessive cigaret smoker. In a joking way it was suggested that she change brands, which she did and all urinary symptoms disappeared within forty-eight hours.

The remaining 7 patients all gave histories of excessive cigaret smoking with symptoms of frequency of two weeks to three months' duration, negative physical and urologic findings with clear urines, and all relieved within sixty-four hours of changing brands of cigarettes.

The eighth patient gave a history of acute bronchitis of four days' duration with sudden onset of frequency day and night—negative urologic findings with clear urine. Examination of a prescription she was taking noted "menthol" as an ingredient. Bearing in mind our experience with the aforementioned 7 cases we suggested changing the prescription and eliminating the menthol. Urinary relief was obtained within twenty-four hours.

One patient with complaints similar to those in the foregoing series had symptoms of frequency which were noted at night and gave a history of taking large doses of barbiturates. With a finding of clear urine it was suggested that she eliminate or change the drug and no detailed examination was made. The patient reported one week later that her symptoms had disappeared.

Another group similar to the foregoing is one in which the subjective symptom is accompanied by an excessive excretion of phosphates or phosphaturia following ingestion of alkalis or citrus fruit juice. Sixteen cases are recorded in this series, all with the same history of frequency of urination day and night, with an average duration of symptoms of two weeks and average weight 165 pounds (75 Kg). The first patient to report demanded hospitalization for a complete physical and urologic examination. The physical findings were unimportant relative to her symptoms and the first urine examination was negative clinically and microscopically. Detailed urologic examination elicited negative findings. We reviewed her history and she admitted that she had been treating with "a fly by night quack," a specialist in dietetics who guaranteed loss of poundage by limiting her diet to an intake of 4 quarts of orange juice daily in addition to his "secret medical formula." Regulation of her diet immediately relieved her symptoms. It is needless to add she was the urologic "guinea pig" for the remaining patients who reported later with the same story and also a factor to add to our urologic oddities that can be classed as primary bladder symptom producers with the finding of negative urine.

CONCLUSIONS

As in other fields of medicine pronounced pathologic disturbances in the bladder are often easy to recognize. It is the milder and less obvious conditions which tax the ingenuity and resourcefulness of the doctor. Many times although the pathologic alteration is not great the functional derangement may be most severe and distressing to the patient. Dysuria often falls into this category, and the cause of the disturbance can be found only by a sympathetic approach to the patient's problem, by attention to detail in the matter of careful and complete history taking and examination and by the use of methods of treatment which have proved their value.

Our experiences in this field demonstrate how varied the causes of dysuria may be and how they can be discovered only by careful study and examination.

PROSTATITIS AND SEMINAL VESICULITIS ACUTE AND CHRONIC

ROY B. HENLINE, M.D.
NEW YORK

Infection of the prostate and seminal vesicles may present a clinical picture varying from that of an acutely ill patient to that of one who is unaware of a smoldering infection. The symptoms and diagnosis of an acute infection of the prostate present little difficulty, but the insidious onset and absence of symptoms pointing to the urinary tract in many chronic infections may fail to attract the patient's or physician's attention to the prostate as the source of infection. Although usually not dangerous to life, chronic prostatic infections may cause suffering and inconvenience out of all proportion to the actual extent of the disease.

Chronic prostatic infections occur with greater frequency than is generally believed. Hinman¹ states that 35 per cent of all adult males have infected prostates. They occur more frequently in middle life—that is, between the ages of 30 and 50. The manifestations may be so capricious with no symptoms referable to the prostate that it becomes a matter of chance during routine examination to discover the prostate as the source of infection. A cardinal principle of surgery is violated in treating these patients by massaging an infected area yet much clinical evidence has accumulated to justify such treatment since most patients may thus be relieved of their infection.

ETIOLOGY

Acute prostatitis and seminal vesiculitis usually develop from an active infection in the posterior urethra. This infection may arise from an acute urethritis, may be secondary to an infection of the upper urinary tract with infected urine, may be metastatic or may result from a general pyemia. The offending organism may be the gonococcus, but any other pyogenic bacteria can produce an acute prostatic infection. An abscess may develop or the process may subside, giving place to an ordinary chronic infection.

Chronic prostatic infections, in most instances, are not caused by the gonococcus. Kretschmer,² in a study of 1,000 cases of chronic prostatitis, identified the gonococcus as the offending organism in only 24. Gram-positive cocci are frequently mistaken for gonococci both in urethral and in prostatic smears and a diagnosis of gonorrhea is erroneously made. Gonococci should be searched for with extreme care before the diagnosis of gonorrhea is made. It is unfortunate that patients as well as many practitioners are of the opinion that chronic prostatitis is preponderantly due to, or the result of, gonorrheal urethritis. This point of view is regrettable since it does an injustice to many patients suffering from chronic prostatitis.

Undoubtedly a certain percentage of cases of chronic prostatic infection result from gonorrhea, even though the gonococcus cannot be demonstrated in the prostatic secretion. Other bacteria are found in the strippings from the prostate, and the role of pre-existing gonorrhea

must remain uncertain. A large percentage of these patients give no history of gonorrhea, and the origin of the infection must be sought for elsewhere. Kretschmer,² in a study of the cultures from 407 patients with chronic prostatic infection, found colon bacilli and staphylococci to be the most frequent organisms. This corresponds with the findings of Hill³ and many other observers. Frequently more than one type of organism is found in the prostatic secretion. In a series of 170 cultures 60 contained two or more organisms, while 22 failed to reveal any bacteria.

In a certain number of cases, chronic prostatitis is the result, or aftermath, of an attack of acute prostatitis. As the acute infection subsides, the prostate remains infected and requires treatment to eradicate the infection completely. Even after an abscess has run its course by absorption or rupture or has been relieved by operation, a certain amount of infection of the prostate usually remains, as may be demonstrated by a careful examination of the strippings.

The prostate may become infected from direct extension of an acute urethritis, the bacteria entering the gland by way of the prostatic ducts. This is the usual method of involvement of the prostate from gonorrhea or from a nonspecific urethritis.

Fig. 1—Pyelogram showing moderate hydronephrosis and pyelonephritis discovered in a patient presenting symptoms of chronic prostatitis.

Distant Foci of Infection—It is a well recognized clinical fact not only that chronic prostatitis may be the focus of infection which produces metastatic disease in remote parts of the body but that the prostate may itself be infected from foci in other parts of the body. It is accepted by most urologists that the prostate may become infected from the teeth, tonsils, intestinal tract, respiratory tract, furuncles and other sources.

The method by which these bacteria reach the prostate has not been proved. Many urologists believe that

This paper, in a symposium on "Office Treatment in Urology," is published under the auspices of the Section on Urology, Philadelphia, W. B. Saunders Company, 1936.

the organisms enter the blood stream and are carried to the prostate directly. Others visualize these absorbed bacteria from various foci entering the blood stream, to be excreted from the kidney, then, during their passage from the kidney through the bladder, some bacteria

Fig. 2.—Pyelogram of same patient as in figure 1 after treatment with urinary antiseptics and dilation of the ureter

lodge in the prostatic ducts, eventually to produce a prostatic infection. There is some evidence to substantiate this theory. It has been shown that pyogenic bacteria may be excreted by the kidney without producing pus or other evidence of infection in the urinary tract in the absence of obstruction. Tuberculosis frequently involves the kidney primarily, then invades the prostate, seminal vesicles and epididymides as the bacteria pass to the bladder in the urine and are voided. If tubercle bacilli follow this sequence, it is argued, why should not other bacteria do likewise? Hill⁴ has shown the frequency with which the same bacteria are found in the urine as are found in the prostatic secretion both by smear and by culture. This suggests that bacteria excreted through the kidneys may be the source of the organisms producing prostatic infections.

This mode of infection is further suggested by patients presenting symptoms of chronic prostatitis who actually have demonstrable infection in one or both kidneys. Usually the renal infection may be suspected by the finding of pus in the first, second and third glasses of voided urine. However, in some instances the second and third glasses of voided urine may be macroscopically clear and the presence of infection in these specimens may be overlooked. In other instances the infection may be absent in some specimens only to appear at a subsequent urine examination. Such a typical case was seen recently. A policeman presented symptoms of chronic prostatitis. His voided urine showed a few pus cells and shreds in the first specimen, but the second and third glasses were normal. On occasional subsequent visits each glass of voided urine showed pus cells. There were no symptoms

referred to his kidneys. After about six weeks of treatment by prostatic massage without complete relief a thorough urologic investigation was carried out. This revealed a moderate infection in his right kidney with some hydronephrosis. The same type of bacteria was cultured from both the kidney and the prostatic stripplings (fig. 1). Adequate treatment directed to this kidney restored it to normal, as evidenced by a pyelogram (fig. 2) and functional tests. With subsequent treatment of his prostate by massage the prostatic secretion became entirely free from infection. It is difficult to evaluate the sequence of events in this case. Whether the kidney infection antedated the prostatic infection or was secondary to it cannot be stated with certainty. However, one should be constantly aware of the possibility that some other focus in the urinary tract may be responsible for failure to obtain results in the treatment of a prostatic infection. Such a focus may constantly reinfest a prostate even during the course of its treatment.

A case of renal tuberculosis may be erroneously diagnosed and treated as a case of chronic prostatitis. Another recent patient had been thus treated, and only a thorough examination revealed the primary source of his infection to be in the kidney (fig. 3). It is true that his prostate was infected, but this local infection was evidently secondary to the renal lesion.

These cases are cited to suggest the possibility of the urinary tract being the means by which bacteria may

Fig. 3.—Pyelogram revealing renal tuberculosis in a patient presenting symptoms of chronic prostatitis for which he had been treated

reach the prostate. Slight recurring attacks of pyelonephritis may go unrecognized or be passed off by the patient as a "cold in the bladder." Subsequent chronic prostatic infections may result from these renal lesions as the bacteria are voided in the urine and a few remain in the prostatic urethra to produce an inflammation.

Sexual Factors—Much has been written on the relationship of sexual abuses to chronic prostatitis. Horseback or bicycle riding, alcohol, sexual overindulgence, withdrawal, prolonged sexual excitement, masturbation and prolonging the sexual act have all been considered factors in the production of chronic prostatitis. Undoubtedly, each may be a predisposing factor by causing congestion of the prostate. However, congestion alone will not produce an infected prostate; bacteria must invade the gland in some manner. Such sexual irregularities may logically be considered to produce a fertile field for the growth of bacteria once they have invaded the prostate. The path of the invading organism is uncertain, but the frequent contact of this congested gland with voided urine may result in the deposition of pathogenic organisms and the production of a prostatic infection.

PATHOLOGY

"Acute prostatitis begins as an acute inflammation of the prostatic ducts and acini and of the overlying posterior urethral mucosa." The seminal vesicles usually also become involved. The infection may subside or it may invade the stroma around the acini, coalesce and form a prostatic abscess.

Chronic prostatitis presents a similar involvement of the prostatic ducts and acini but is less acute in its onset and runs a more protracted course. The virulence of the invading organism is not so pronounced and the prostatic ducts are less likely to be occluded early in the infection. The stroma may be invaded and, if uninterrupted by treatment, this invasion may finally progress to the formation of prostatic sclerosis. Hyams⁵ failed to find inflammation of the seminal vesicles without similar involvement of the prostate, yet prostatic infection does occur without either seminal vesicle being affected. It therefore must be uncommon for the seminal vesicle to be the focus of an infection in the absence of prostatic disease.

SYMPTOMS

Acute prostatitis is ushered in by severe urinary distress. The voided urine is cloudy from pus since an accompanying urethritis and cystitis are usually present. Urethral discharge may be profuse or absent, depending on the drainage from the prostatic ducts. Pain, fever, chills and frequent, difficult urination are present in varying degrees. Complete urinary retention may occur and, when it does, is suggestive of the formation of an abscess.

The symptoms of chronic prostatitis and seminal vesiculitis may not so readily attract attention to the affected area. In many instances, attention is directed to the prostate by the history and urinary symptoms, on the other hand, the absence of urinary symptoms and findings may fail to suggest a prostatic infection. In general, the subjective symptoms may be divided into three groups: (1) predominantly urinary symptoms, (2) symptoms, resulting from chronic prostatic infection, referable not to the prostate or urinary tract but to distant parts of the body and (3) some form of sexual dysfunction.

Patients with predominantly urinary symptoms (group 1) comprise the largest number. The symptoms immediately attract attention to the urinary tract

as the source of the infection. A mild urethral discharge may be the only presenting symptom of chronic prostatitis, and these patients are fearful that they have contracted gonorrhea. The urethral discharge is frequently caused by an infected prostate or seminal vesicle spilling some of its organisms into the urethra, to produce a urethritis. A careful microscopic examination of such a urethral discharge is imperative before one is justified in making a diagnosis of gonorrhea. The character of this discharge is extremely variable, but the discharge is usually less in quantity and more "sticky" or thinner than that present in gonorrheal urethritis. Such a discharge is found in almost 40 per cent of cases. Frequency of urination is often present and suggests the posterior urethritis so frequently encountered in prostatic infections. Any type of urinary symptoms may be present in chronic prostatitis, but none are pathognomonic of the disease. The intimate relationship of the prostate to the bladder neck would lead one to expect an infection of the gland to produce urinary symptoms. These may be quite severe, very mild or entirely absent. Pain of varying degree may also be present in the prostate. It is usually mild although at times it is described as really severe. Pain caused by the prostate may be referred to the perineum, urethra, penis or rectum and may be aggravated by sitting on a hard chair. Relief may occasionally be obtained by crossing the knees or by making pressure on the perineum.

In group 2 are patients who may be classified as having a "silent prostate" since no symptoms are referable to the urinary tract or the prostate, yet the prostate and seminal vesicles may be the foci of infection for some distant lesion. Among the common lesions for which the prostatic infection may be responsible are arthritis, bursitis, myositis, neuritis and iritis. When seeking for foci of infection, the prostate and seminal vesicles should be considered as routinely as the teeth, tonsils or sinuses. Early recognition of such a focus before irreparable damage has been done is important. Pain from prostatic infection is usually referred to the lower lumbar region or perineum but may occur anywhere in the pelvic region or down the legs. These vague symptoms are so common that one should routinely examine the prostate as a possible source of infection in patients manifesting them.

These indefinite pains may be so slight that the patient may be unaware that he is not quite normal. He may attribute them to "rheumatism" or a "strain" and it is astonishing how long these discomforts will be endured before the patient seeks advice as to the real cause of his trouble. The effect on the nervous system may become quite definite and true neuroses may make their appearance. The patient becomes restless, complains of lack of concentration and may feel that he is becoming prematurely senile. His anxiety as to the future and the constant feeling of ill health may provoke other varied symptoms. Gastrointestinal manifestations may appear, and "dyspepsia" or flatulence may be prominent. Unfortunately in many of these cases there is nothing either in the history or in the symptoms to suggest a chronic prostatic infection as the cause of the disturbances.

Symptoms of sexual dysfunction (group 3) are fairly common, but in view of the fact that the prostate is a sexual gland, and considering the prevalence of prostatic infections, it is remarkable that sexual symptoms

⁵ Keyes, E. L. *Urology*, New York, D. Appleton & Co., 1928.
⁶ Hyams, J. A., Kramer, S. E., and McCarthy, J. F. *The Seminal Vesicles and the Ejaculatory Ducts*, J. A. M. A. 98: 691-696 (Feb. 27) 1932.

are not more frequent and severe than they are. Undoubtedly some sexual disorders are caused or aggravated by chronic prostatitis, since treatment of the prostate occasionally results in considerable benefit of the sexual symptoms. However, so many factors are involved in most sexual dysfunctions that it is difficult to evaluate the primary cause. Certainly one should investigate the prostate carefully and attempt to rid it of any infection. According to Kretschmer,⁷ premature ejaculations, loss of desire and weak erections are most commonly complained of by patients manifesting chronic prostatic infections.

DIAGNOSIS

In acute prostatitis and seminal vesiculitis any manipulation by rectum must be gentle, and massage and stripping are contraindicated. The history usually gives presumptive evidence of an acute infection and urinary symptoms are referable to the seminal tract. Acute febrile reactions depend on the severity of the attack. The urine, even when voided in three glasses, is usually cloudy from pus. Careful rectal palpation will reveal a swollen, hot, tense prostate. Instrumentation should be avoided until the acute symptoms have subsided, but repeated gentle palpation of the prostate may be necessary for the diagnosis of prostatic abscess.

The diagnosis of chronic prostatitis is based on the findings of rectal examination and the microscopic examination of expressed prostatic fluid. The voided urine frequently contains shreds and occasionally some pus, although it may be entirely normal. The history may not give any evidence of a prostatic infection, and careful rectal palpation with repeated massages may be necessary to obtain pus in the prostatic fluid. The first gentle prostatic massage may express the fluid from those ducts which are uninfected, and the strippings may appear normal under the microscope. The infected ducts may be temporarily occluded by pus and debris, and two or three or even four examinations, at three to five day intervals, may be required to obtain strippings from all the prostatic ducts. Thus one may be uncertain of the presence of pus in the prostatic fluid obtained from a single examination. Although some urologists do not agree, Hinman¹ states that "the trauma of three repeated prostatic examinations (on alternate days) will not in itself cause the appearance of pus in the secretion if infection is absent at the start." These repeated examinations may stir up a latent or hidden focus which might otherwise be missed.

Many different positions for the patient to assume for palpation or massage of the prostate have been recommended. I myself prefer to have the patient kneel on a table, with the buttocks extended and the head down to a level with the knees. With the patient in this position the physician may palpate the prostate and seminal vesicles more completely, with less pain to the patient. The gloved finger, well lubricated, should be inserted very slowly past the rectal sphincter. When this careful procedure is followed, the patient will be less likely to draw away from the examiner, and he will be extremely grateful for one's gentleness. The shock of suddenly dilating the rectal sphincter may be much greater than that of massaging the prostate.

Often there is a decided discrepancy between the gross palpable changes in the prostate and the degree of infection manifested in the strippings. The examining finger may detect no gross change in the size or consistency of the prostate, yet it may be infected.

More frequently the prostate is one or more of the following: enlarged, irregular in outline, nodular, boggy, indurated, with an occasional area of softness, and surrounded by adhesions from periprostatic inflammation. Normally the two lateral lobes, which are palpable by rectum, should be smooth on the surface, firm in consistency with a dividing median sulcus and freely movable from side to side. Each lobe should be about the size of the distal phalanx of the thumb.

The normal fluid expressed from the prostate is opalescent, slightly alkaline to litmus, filled with minute, translucent, lecithin bodies (somewhat smaller than red blood cells) and contains some epithelial cells, a few corpora amylacea, often spermatozoa and less than 10 leukocytes per high power field. One should not be misled in obtaining a normal secretion on first examination, particularly if rectal palpation gives evidence of an abnormal prostate.

The diagnosis of chronic prostatitis is established with the finding of an increased number of leukocytes in the prostatic strippings, particularly if they are seen in clumps. It is usual for the quantity of lecithin bodies to be decreased in the presence of many pus cells and, as improvement occurs, the leukocytes decrease in number and the lecithin bodies increase. Brunet and his associates⁷ suggest the use of the peroxidase stain for prostatic secretions. This stain readily differentiates granular cells and lymphocytes from polymorphonuclear leukocytes. Trattner⁸ has recently devised a "partition catheter" for the purpose of temporarily excluding the prostatic urethra from the distal urethra and the bladder. Between these two inflated bulbs are openings in the catheter which may be injected with a contrast medium to visualize the prostatic ducts by x-ray, or antiseptic solutions may be forcibly injected through them into the deep recesses in the prostate. He urges extreme care in the use of this catheter, since these solutions may be forced into the blood stream or into the ejaculatory ducts to produce epididymitis.

It should again be stressed that the prostate deserves to be considered a possible focus of infection just as much as the teeth or tonsils. The prostate is more likely to be overlooked when urinary symptoms are not present and the voided urine is normal. Every physician is aware that the small, buried tonsil is as dangerous a focus of infection as the huge tonsil with infected follicles. The prostate too may be harboring an infection which may be absorbed by the blood stream, and yet none of the infected material escapes through the prostatic ducts to produce urinary symptoms and give evidence of infection in the voided urine. Every practitioner should make proper examination of the prostate a routine procedure when searching for a focus of infection.

COMPLICATIONS

The mere finding of an abnormal prostate by rectal palpation and pus in the strippings from it, should not conclude an investigation. Although the diagnosis of chronic prostatitis is thus established, one should seek the cause of the infection and attempt to eliminate factors which may prevent its ready response to treatment. Response to local treatment should not be expected,

7 Brunet W, M Shaw N, D Reinhardt C H and Anday L J. Chronic Prostatitis. A Clinical Review of 100 Cases in Which the Fresh and Peroxidase Stained Secretions Were Studied. *Virginia M Monthly* 69: 619-625 (Nov.) 1942.

8 Trattner B R. The Introduction of Solution into the Tubuloalveolar System of the Prostate Gland. *J Urol* 45: 710 (Dec.) 1942.

when the prostate is being constantly infected from an infected tooth or tonsil unless the source of the infection is first eliminated. Neither will a prostate respond to local treatment when a posterior urethritis, urethral stricture, cystitis or renal infection is present without adequate treatment of the complicating condition.

In the presence of an acute or a subacute infection of the prostate it is unwise to examine the remainder of the urinary tract. Even in the presence of chronic prostatitis it frequently is better to treat this infection for a reasonable time before resorting to a more thorough study of the urinary tract. However, one should not persist with local treatment when satisfactory response is not obtained without seeking for some coexisting complication. In fact such complications are so common that many urologists prefer to consider chronic prostatitis as a symptom of a secondary infection from some focus the finding and elimination of which is essential to adequate and permanent relief. To discover the origin of such a primary infection often requires diligent and persistent search but the problem should constantly be before one while treating chronic prostatic infections.

Besides the teeth and tonsils the intestinal tract, gall-bladder, cutaneous infections or perirectal infections may be the source of an infected prostate. Within the urinary tract almost any infective process may produce a prostatic infection and prevent the response of the latter to treatment. Among the more common causes are urethral strictures (often of large caliber) lesions of the urethra, chronic urethritis, urinary retention from hyperplasia or a fibrous bladder neck, vesical diverticula, prostatic calculi, chronic renal infections, tuberculosis, diabetes and syphilis. Careful observation of the voided urine should be made on each visit, preferably in two or three glasses. Evidence of infection in the second and third glass is suggestive of an infection of the upper urinary tract yet such evidence may not be obtained at all times, as is the case when an intermittent pyelonephritis is present. A test for residual urine should be made from time to time. In short, when symptoms of chronic prostatitis are not relieved and the strippings do not show definite improvement within six weeks after a biweekly course of prostatic massage has been instituted, one should carefully search the urinary tract for a reason why the response has not been satisfactory. To persist with massage for prolonged periods is rarely necessary and suggests that a focus of infection may have been overlooked.

Failure to establish normal sexual hygiene may interfere with the improvement in chronic prostatic infections. On the other hand, the most careful and diligent search may fail to reveal the source of the infection in chronic prostatitis.

Before the diagnosis of chronic prostatitis can be properly established, it is necessary to rule out other lesions of the prostate. A tuberculous prostate usually presents an irregular nodular surface to palpation. It is almost always secondary to tuberculosis elsewhere in the urogenital tract, and careful search may reveal tubercle bacilli in the urine or, less frequently, in the prostatic strippings. Prostatic calculi may be suspected by palpating crepitation within the prostate and can be confirmed by x-ray examination. Advanced carcinoma of the prostate presents a stony hard induration. Early

carcinoma is also hard but may be limited to a small pea sized area readily palpated at rectal examination. These conditions should be ruled out, if possible, before treatment is undertaken. A hard nodule in the prostate may require surgical perineal exposure with biopsy to confirm the diagnosis.

TREATMENT

Acute Prostatitis—The treatment of acute prostatitis is by heat and protection from trauma and that of subacute and chronic prostatitis by prostatic massage. The sulfonamides are often helpful in either condition but cannot be relied on to the exclusion of local treatment.

Acute prostatitis whatever the cause, is best treated by complete bed rest for all febrile cases and the avoidance of foods which irritate the urinary tract. Sexual excitation should be avoided and all local treatment such as urethral or bladder irrigations and rectal manipulation should be discontinued. Heat is beneficial and may be obtained by hot sitz baths by the application of heat directly to the prostate, by rectal irrigations or by electric prostatic heaters or diathermy. The Bransford Lewis electric device has given satisfactory results. Herring⁹ advocates diathermy with proper orificial electrodes as the method which will obtain the greatest elevation of local temperature to the prostate. The bowels should be kept well open to avoid the pressure of a hard stool against the prostate. Only the most gentle palpation should be done to diagnose the development of a prostatic abscess. The sulfonamides are usually very effective in relieving acute prostatitis. Sulfathiazole if tolerated usually is most effective when given in 1 Gm. doses every four hours, together with sufficient alkalis such as sodium bicarbonate. The urinary output should be measured and maintained at a minimum of 1,500 cc. daily. Sulfonamide medication should rarely be given for more than ten days, and blood studies should be made if prolonged treatment becomes necessary. Following the subsidence of acute symptoms local treatment may be carefully instituted.

Chronic Prostatitis—The treatment of chronic prostatitis revolves around the principle of establishing adequate drainage of the infected prostatic ducts. In some instances this is readily accomplished, in others it is difficult to attain, while in cases presenting pronounced sclerotic changes the establishment of drainage of all the infected areas may be impossible with any type of local treatment.

Local Treatment—Once the diagnosis of chronic prostatitis has been established massage of the prostate by the rectum is the most important single measure to be employed in its treatment. Although massage of an infected area may seem unphysiologic, urologists have achieved considerable success in the systematic treatment of these infections. This method of treatment is universally adopted by all urologists, yet some difference of opinion exists as to the frequency with which such massage should be carried out. As a rule we massage the prostate twice a week, and as the amount of pus diminishes the treatments are given less frequently.

The first object of prostatic massage is to increase the blood supply to the prostate and in this way aid in carrying away infection and stimulating absorption. The second purpose is to evacuate pus, bacteria and

⁹ Herring, J. B. Heat Producing Appliances. Their Comparative Value in the Treatment of Prostatic Infection. *California & West Med* 45: 140 (Aug.) 1936.

debris from the prostatic ducts. Too frequent or too vigorous massages may defeat these purposes and may even produce an acute infection in the prostate or epididymides.

Some urologists prefer to massage the seminal vesicles and prostate before the patient voids his urine, after which the urine flushes the prostatic fluid from the urethra. Others instil an antiseptic solution into the bladder and posterior urethra after prostatic massage with the expectation that some of the solution may find its way into the emptied prostatic ducts. Still others instil an antiseptic solution into the bladder through a catheter before massaging the prostate, hoping thereby to prevent the expressed infected material from infecting the bladder or urethra. Although each method may have some advantage in certain instances, voiding after massage is satisfactory in most cases.

Massage of both the seminal vesicles and the prostate should always be performed together. With the patient kneeling in the knee-chest position, the gloved index finger well lubricated is gently and slowly inserted into the rectum as far as possible. Pressure is begun above the prostate on one side as the finger is withdrawn to the prostate. This is repeated several times and followed by the same procedure over the other vesicle. The finger is then brought down to the prostate and several strokes are made over the gland on either side from the uppermost part of the prostate downward and toward the midline. The massage is concluded by several strokes over the midline to express the fluid from the main ducts into the urethra. The prostatic fluid appears at the urethral meatus and is collected on a glass slide for examination. While gentleness is imperative during the first few massages, more firm pressure may be required in those cases which fail to respond to treatment.

The next most important element in the local treatment of chronic prostatitis is the search for and treatment of urethral stricture. This is particularly necessary if symptoms of a chronic urethritis are present. The great frequency with which prostatitis is associated with urethral stricture should lead one to search for both lesions in every patient. Often the treatment of either the urethral stricture or the prostatic infection is continued without searching for its associated lesion. Urethral dilation is never undertaken in an acute urethritis, but in the presence of a few shreds and pus cells in the urine the passage of sounds is very beneficial. Even when a definite stricture cannot be found, dilations will serve to promote better drainage from the prostatic ducts. It is preferable to pass but one sound at a single treatment and not repeat the procedure more than once a week. Too enthusiastic treatment may produce complications and retard the favorable progress of the disease. If care is used in the passage of urethral instruments, any subsequent increase in symptoms may be considered to result from the activating of a dormant infection in the urethra or prostate and not to be caused by the passage of a sterile instrument into the bladder. Increase in the urethral discharge may follow instrumentation of the urethra, or chills, fever and sweats may supervene from stirring up a smoldering infection in the genital tract.

The value of urethral dilations is commonly seen in chronic prostatic infections with symptoms of posterior urethritis. Recently a patient had been treated by

prostatic massage twice weekly for six weeks. His symptoms failed to subside and he was relieved only after the passage of sounds. Furthermore, his prostatic infection began to improve more promptly after his urethral dilations.

Many methods have been advocated for applying heat to chronic prostatic infections. When symptoms are severe, considerable relief may be obtained from local heat. An electric pad or hot water bottle applied to the perineum is helpful. Hot rectal douches are advocated by some but are rarely required in chronic infections of the prostate. Various prostatic heaters and electric devices have their advocates and are helpful in some cases. However, Herring¹⁰ has shown that most of these commonly used methods fail to produce heat in the prostate. Although symptoms are frequently improved by the application of local heat, the actual benefit to an infected prostate is problematic.

The use of strong solutions and astringents has fallen into disrepute. Vaccines have seldom, if ever, added anything of value to the treatment of these cases.

The treatment of chronic prostatitis by intraprostatic injections has been advocated by Grant¹⁰ in recent years. The prostate is injected with a needle inserted through the perineum and guided by a finger in the rectum. Various antiseptic and sclerosing solutions have been used with reported success. However, O'Connor¹¹ in an experimental study showed that any solution thus injected produced a sclerosis and left infected areas in the prostate with their normal drainage ducts occluded. This method of treatment also has few advocates.

The use of the sulfonamides has been helpful in eradicating the infection from the prostate in certain cases. When fibrosis is present within the prostate, any blood borne medication, such as the sulfonamides, will likely prove to be of little if any benefit. It is my practice to give sulfathiazole (1 Gm. four times daily for ten days) in these cases while prostatic massage is being carried out. If no benefit results in that time, it will rarely be helpful to continue the medication. I believe it is also desirable to administer one of the sulfonamides for twenty-four hours before and after urethral dilations. Whether this benefits the local infection is doubtful, but it should reduce the incidence of epididymitis. Actually, epididymitis from prostatic and urethral infections is becoming rare.

Other complications in the urinary tract besides urethral stricture may prevent one from obtaining a satisfactory response from local treatment to the prostate. A narrow meatus demands a meatotomy so that adequate urethral dilation may be carried out. Urethroscopic examination may reveal local infected crypts along the urethra which may cause urinary symptoms with shreds and pus in the urine. Polyps or granulation tissue are frequently found in the posterior urethra. Prostatic calculi may be present and unsuspected from rectal palpation and may require x-ray examination for their detection. Fibrosis or even a prostatic bar may interfere with adequate drainage from the prostatic ducts. A superimposed hyperplasia of the prostate may act in a similar manner. Tuberculosis, diabetes or syphilis may prevent a favorable response.

11. O'Connor, A. J. and Ladd, R. I. Intraprostatic Injection. *J. A. M. A.* 107: 1185-1188 (Oct. 10) 1936.

to local treatment. Finally, any infection in the kidneys, ureter or bladder may re infect the prostate, so that local treatment will not suffice to cure the prostatic infection. While it is true that most of these infections are readily suspected from pus in the second or third glass of voided urine, the infection may be so mild as to escape the examiner's attention unless a careful microscopic study of each glass of voided urine is performed. Renal symptoms are frequently entirely lacking. Pyelonephritis may occur intermittently in such a mild form as to escape notice by the patient or physician, yet enough bacteria may be excreted in the urine to re infect the prostate. Such bacteria may even be excreted without the presence of pus in the urine, and stains or cultures of the urine are necessary for their detection. Their intermittent excretion may require careful study to evaluate their significance. When such doubt exists a complete urologic study is indicated.

The prostate may become infected from a distant focus of infection. Cabot¹² believes that 95 per cent of such cases are secondary to infections in the teeth and tonsils. Acute upper respiratory or intestinal infections may also produce a prostatic infection. If the original focus is discovered and removed, the prostatic infection will then become the primary focus of infection, but if the prostatic infection is treated without removing the original focus, the response to treatment will be slow and recurrences likely. In treating such cases, the elimination of the original focus, followed by adequate treatment of the prostate, is indicated.

Severe local and distant reactions may occur following massage of a prostate which is the seat of a focal infective prostatitis. When following prostatic massage an exacerbation of symptoms occurs in a case of arthritis, iritis, neuritis and the like, it is suggestive evidence that the prostatic infection is responsible for the distant lesion. Very gentle massage should be carried out for the first few treatments, since vigorous treatment may occasion such a severe general and focal reaction that irreparable damage may result. These reactions are probably due to specific toxins forced into the blood of a patient already sensitive to them.

Chronic prostatitis is frequently present in patients presenting symptoms of sexual dysfunction. The role that this infection plays in the production of these symptoms is not thoroughly established. Certainly treatment of such infections is followed by improvement in symptoms in some cases, while in others there fails to be any response. The complexity of symptoms and the multitude of causes for such disturbances call for a thorough study of the individual case and the institution of appropriate treatment. When a diseased prostate is discovered, it should be treated in order to eliminate at least one factor in the production of sexual symptoms. Glandular therapy, encouragement and psychotherapy are other forms of treatment which may be beneficial.

General Treatment—Patients with chronic prostatitis are usually urged to avoid highly seasoned foods, spices and strong alcoholic drinks, since these may irritate the urinary tract. I have not been convinced of the necessity for such restrictions except for moderation in alcoholic beverages. The patient should be urged to drink substantial amounts of fluids. The bowels should

move at least once a day to prevent congestion around the prostate from impacted fecal contents.

Advice concerning sexual relations should depend on the severity of the infection. It is often wise to avoid sexual excitement when symptoms are moderately acute, yet regular sexual habits should be urged when the symptoms have begun to respond to treatment. Irregular sexual practices and overindulgence should be avoided. Massage may take the place of sexual hygiene in the early stages of treatment, but is at best a poor substitute for it. The quantity of prostatic fluid expressed by massage is much less than is contained in a normal ejaculate. Normal intercourse should aid in the treatment of nonspecific prostatitis and should be permitted while massage is being carried out.

The sulfonamides are helpful in the treatment of certain cases of chronic prostatitis but should not be used to the exclusion of local treatment. Prolonged use of these drugs will not aid in the treatment and may prevent a normal response from being obtained by massage. Recently a patient had been taking sulfonamides for two months and his symptoms and prostatic secretion were becoming progressively worse. His blood count showed 3 800 000 red blood cells and 3 700 white blood cells with 70 per cent lymphocytes. Discontinuance of the drug caused a prompt return of his blood count to normal and subsequent improvement in his infection.

PROGNOSIS

The response to treatment in chronic prostatitis and seminal vesiculitis may be slow, and the patience of both the patient and the physician may be taxed to the utmost. Persistent massage may be required for long periods but should be spaced with vacations from treatment. The goal should be the elimination of pus from the prostatic strippings. In general, the outlook in the treatment of these patients is good, provided the cooperation of the patient can be maintained. It is better to discuss the possibility of prolonged treatment with the patient at the outset so that discouragement may be avoided at a later period.

The prognosis in chronic prostatitis depends largely on the cause and the degree to which the infection has progressed. If the cause can be ascertained and corrected and the prostate is soft and boggy, the outlook should be good. If the origin of the infection is vague and the infection has progressed to the formation of considerable scar tissue in the prostate or to the development of a fibrous bar or prostatic calculi, conservative treatment will likely not eliminate the infection.

One should constantly seek the origin of the infection, whether it is from an acute local infection or a distant focus, since elimination of such an area materially alters the prognosis. In many instances this is difficult to ascertain and study of the patient may be required for some time to arrive at a conclusion. In some cases careful diligent search for the cause may be unavailing. Repeated urine examinations may lead one to a suspected source of infection.

If the prostate has been the seat of prolonged inflammatory changes, it will probably not return to normal. However, treatment and periodic observations may keep the infection to a minimum and prevent the recurrence of symptoms. When careful complete search for complications fails to disclose any contributing factor to the cause or continuance of a prostatic infection and

¹² Cabot, Hugh. *Modern Urology*, Philadelphia, Lea & Febiger, 1936, vol. 1.

when repeated courses of prostatic massage fail to eliminate pus cells from the strippings completely and when definite symptoms referable to the prostate are absent local treatment should be discontinued. If sufficient damage to the prostate has occurred such as the production of fibrosis at the vesical orifice or symptom producing prostatic calculi surgery may be indicated.

In focal infective prostatitis the prognosis depends mainly on the finding and elimination of the original focus of infection following which local treatment to the prostate should clear up the infection in most instances.

Brunet and his associates recently reported the results of treatment in 100 cases of chronic prostatitis. In 60 cases there was complete relief, with return to normal of the prostatic secretion. In another 24 the symptoms were relieved but the prostatic strippings still contained some pus. In the remaining 16 clinical improvement was not noted, but these patients all complained of some sexual dysfunction. These were not further analyzed but at least this percentage of cures should be obtained.

The outlook for patients with sexual dysfunction is difficult to evaluate. A multitude of factors may be responsible for the symptoms complained of by these patients. Although chronic prostatitis may be a factor, there are almost invariably other factors of even greater importance to evaluate and treat. Among these may be mentioned hypotension, low metabolic rate and vitamin deficiency. Psychotherapy is frequently indicated, and this treatment may often be intelligently performed by the urologist.

SUMMARY

1 Chronic prostatic infections are of common occurrence and by far the greatest percentage of cases are not caused by gonorrhea. Infection in the prostate occurs more frequently from a distant focus of infection or from some nonspecific infection in the urinary tract. Lack of sexual hygiene may be a predisposing factor in the development of a prostatic infection.

2 Urinary and genital symptoms frequently attract attention to the prostate as the source of the infection. In many instances chronic prostatitis presents no local or urinary symptoms, and attention is not attracted to the prostate. A careful prostatic examination is required to determine that the prostate is a focus of infection for symptoms elsewhere in the body.

3 The diagnosis of chronic prostatitis is made by rectal palpation and the finding of pus in the expressed prostatic secretion by microscopic examination.

4 The origin of the infection should be carefully sought for and eliminated. Prostatic massage with general hygiene together with sulfonamide therapy, will usually eradicate the infection, although prolonged treatment may be required.

5 Complications in the urinary tract are common and should also be treated to obtain the best results from local treatment to the prostate. Among the most frequent are urethral stricture, posterior urethritis and mild chronic renal infection.

6 Infection of the prostate is so common and the prostate is so often the seat of a focus of infection that routine examination of this gland should be undertaken as frequently as that of the teeth and tonsils.

901 Lexington Avenue

INDICATIONS FOR VISUAL EXAMINATION OF LOWER URINARY TRACT

H. C. BUMPUS JR., M.D.
PASADENA, CALIF.

Those of the profession who have personally undergone what in the vernacular of our trade, is termed a "cystoscopic examination," appreciate that, like the holy bonds of matrimony, it is not something to be undertaken lightly. The question is too frequently asked "Can my patient stand a cystoscopic examination?" because it is not appreciated that when such an examination is made by a trained, skilful and experienced operator, even as an office procedure, it can give valuable information obtainable in no other way and without serious discomfort or untoward aftermath. If attempted by the untrained and heavy handed, the after-effects may be slow in disappearing and the experience long remembered with horror. The narratives of patients who have undergone this modern form of torture are so distressing that after a "referring doctor" has listened to one or two he naturally becomes reluctant to subject others to such an examination unless the indications render the procedure imperative. This is regrettable, because valuable information regarding developing pathologic changes may be unnecessarily delayed. Because of this hesitancy to refer patients for a visual examination of their lower urinary tract, it is important for the general practitioner to be familiar not only with the indications that warrant cystoscopy but to know clinical conditions in which visual examination of the lower urinary tract is not only unnecessary but absolutely contraindicated. For under certain conditions the passage of a rigid instrument, such as a cystoscope, into the lower urinary tract might result in trauma and subsequent infection of serious moment.

The examiner who expects all his patients to fit a single cystoscope is to be censured. Such expectation might have been excusable a generation ago, but today, with ample equipment available, there is no excuse for one to endeavor to pass a large caliber instrument through a small caliber urethra. The dilation of urethras by sounds in order to make them fit cystoscopes, instead of using cystoscopes of suitable size, has caused much of the dread of this form of clinical investigation. Moreover, different cystoscopes are designed for different types of work, and the examiner who is not capable of utilizing the proper instrument handicaps himself and may, by being thus handicapped, fail to obtain the information most desired. The cystoscope is a highly specialized instrument, it is not a "combination tool" of general utility. The examiner who has limited himself to the use of only a single type of cystoscope not alone handicaps his ability properly to observe but, by attempting to use instruments unsuited to their purpose, causes trauma through the unnecessary prolongation of the procedure. Such injury is not alone painful at the time of its infliction but may result in prolonged suffering. An examiner who compels his patient to lie on the table, with a rigid instrument like a cystoscope in his urethra, while the roentgenologist gets him into position for pyelography, belongs to the horse and buggy era of his

specialty. As soon as ureteral catheters are passed, the cystoscope should be withdrawn immediately. The soft ureteral catheters traversing the urethra will cause no trauma, while a rigid steel tube left in any longer than is absolutely necessary simply prolongs injury and discomfort. The shadow of a cystoscope in the bladder on an x-ray film is the trademark of an inefficient examiner.

Exposure of the genitalia during visualization of the lower urinary tract is an embarrassment to which the patient should not be subjected. It may be avoided by proper and simple draping as follows. The female patient is placed on the table in the lithotomy position; her legs are covered by leggings which reach to the thighs and the external genitalia are cleansed with 'green soap' and warm water and wiped dry. Two sterile towels are draped over the inner surface of the thighs so as to overlap slightly at the vulva and a third towel is placed crosswise on the lower part of the abdomen. The nurse separates the labia with the edges of the overlapping towels just long enough to permit the introduction of the instrument after which the towels naturally fall together.

THE ANESTHETIC

To reduce the discomfort of cystoscopy the choice of anesthesia is naturally of importance. To carry out the procedure painlessly insures better cooperation on the part of the patient and assists in the acquisition of reliable information. It is comparatively easy to examine the interior of the bladder successfully when the patient is relaxed and free from pain. To do so with a struggling, straining suffering person is wellnigh impossible. In the female patient a cotton applicator dipped in 10 per cent solution of cocaine and placed in the urethra for five or ten minutes, before the passage of instruments has become a routine procedure. Yet in so simple a procedure—usually left to a nurse—differences in the results may be obtained. If the swab is too large for the urethral meatus and not lubricated, its vigorous insertion by a careless nurse may cause acute discomfort. To carry out the procedure properly, topical application of some of the 10 per cent solution should first be applied to the meatus, then the swab, well lubricated as well as saturated with the 10 per cent cocaine solution should be gently inserted for a short distance into the urethra. When a few minutes have elapsed a second swab should be inserted still farther. If this procedure is followed out, little discomfort will result when the cystoscope is passed. If, in addition, a few cubic centimeters of one of the cocaine derivatives is injected into the bladder in order to anesthetize the trigone, the entire procedure loses most of its discomfort. For such use procaine hydrochloride is useless. The fact that it has no effect on mucous surfaces is frequently overlooked. The dangers associated with the use of cocaine are apt to be exaggerated but they should not be disregarded. It is well to remember that its anesthetic action, when applied to mucous surfaces, is greater than any of its allies. Its rapid deterioration in solution and the formation of toxic substances make the injection of any stock solution into as highly absorbable an area as the posterior urethra highly dangerous. When cocaine is used, it should therefore be made up fresh for each patient. The dissolving of two 2¼ grain (0.15 Gm.) tablets in an ounce (30 cc.) of sterile water immediately before injection into the male urethra has proved in many thousands of cases to produce the most

efficient local anesthetic. When this is injected, any excessive amount of hydrostatic pressure or the too rapid injection of the solution should be assiduously avoided. As soon as the urethra is well dilated a penis clamp is applied, after which the meatus, as in the female, may be treated with a swab dipped in a 10 per cent solution. When the urethra has been recently traumatized, as by the passage of sounds or other instruments and in all cases in which there is any question of idiosyncrasy for the drug one of the cocaine allies may be used. These have the advantage over cocaine that they do not lose their anesthetic power on boiling and so are easier to sterilize. They do not deteriorate and become toxic when left in stock solution and are therefore more readily available. The most frequently used of such solutions at present are 2 per cent solution of Intracaine and a 4 per cent solution of metycaine. Diathane is also very efficient as a local anesthetic but immediately after injection it produces a burning sensation which is most annoying.

When excessive irritability of the urethra and bladder mucosa has not resulted from either acute or chronic infections as in tuberculosis such anesthetics will render skilled examinations of the lower urinary tract practically painless. If the office affords facilities for recovery from complete narcosis of course no anesthetic is as satisfactory for such work as pentothal sodium. If it is administered by slow and constant intravenous injection in just sufficient amount to keep the patient unconscious, his recovery from the narcosis may be so rapid as to permit him to leave the examining table as well as the office as an ambulatory patient. In such a case it is imperative to have relatives or friends accompany him. The fortifying of pentothal anesthesia by pentobarbital sodium or morphine is contraindicated. It only prolongs the time the patient is incapacitated and adds nothing to the anesthesia. Moreover, by prolonging the patient's inability to cooperate it makes the taking of clear pyelograms difficult.

Because of the disadvantages of having the patient unconscious and unable to cooperate, some urologists prefer to use caudal anesthesia in small enough doses so that the patient is ambulatory after a short period of recovery. The inability of some patients to regain the full use of their lower extremities for a more extended period is the chief objection to this type of anesthesia, as is the occasional occurrence of a rather sharp drop in blood pressure following its application. For the greater number of male patients instillation anesthesia as described is the most generally employed not because it is the most efficient, but because it is the most rapid and easy of application.

PRESENCE OF INFECTION

A microscopic examination of the catheterized urine in the female furnishes the chief indication for or against visual examination of the lower urinary tract. If the urine is highly infected, containing considerable numbers of pus cells it should be stained by the Gram method as a matter of routine to determine what types of organisms are present. Nothing is so likely to cause a patient to be severely ill with chills and high fever as cystoscopy in the presence of infection, especially if it is acute and trauma results from the passage of instruments or the overdistention of the bladder or renal pelves. Therefore, before instrumental examination is undertaken in either sex the type of infecting organism should be ascertained by stain and culture and every

effort made to render the urine bacteriostatic, at least to the specific organisms before proceeding to investigate the damage they have caused. The general habit of subjecting patients to cystoscopy before undertaking to render their urine bactericidal explains to a large extent the dread of the examination so many have developed because of its delayed febrile reactions.

If the history and physical findings as well as the examination of the urine indicate that one is dealing with a tuberculous infection, the experienced urologist will realize at once that the examination will probably be exceedingly painful unless precautions are taken. Few inflammations are more painful than a bladder mucosa irritated by tuberculous toxins. With such patients it is always preferable to employ the most efficient anesthesia. This is done, not alone to lessen the suffering of the patient, but to aid the examination. To permit satisfactory examination of a diseased bladder its owner must be free of pain. The attempts to examine inflamed and infected lower urinary tracts without adequate anesthesia is responsible for more mistaken diagnoses than any other single factor.

To infect a normal urinary tract it is necessary to traumatize it. Experiments have shown that its exposure to bacteria without trauma will not cause infection. One is inclined to conclude that the passage of instruments is the most common cause of trauma. True it is a common cause, it should be avoided by first filling the urethra with a suitable lubricant or lubricating the instrument most thoroughly and passing it with great care and gentleness. A more frequent cause of trauma is the overdistention of the bladder resulting in spasm. The instrument may be passed with skill but when the bladder is filled beyond comfort trauma is produced, which in the presence of infection will be followed inevitably by fever and chills. When the examiner has discovered a pathologic process in the urinary tract, nothing but added trauma is gained by long continued gazing at it. Once the lesion is observed, the examination is concluded as far as diagnosis is concerned. Such observation should require at the most but a few minutes. The report of cystoscopy consuming from fifteen to thirty minutes' duration reflects the inexperience of the examiner and in no way indicates his thoroughness or efficiency.

X-RAY EXAMINATION

It is being more and more generally recognized that many pathologic conditions of the lower urinary tract formerly believed to require visualization for their proper examination can now be as accurately diagnosed by other means. I refer particularly to prostatic obstruction. All cystoscopic instruments are rigid instruments, and all enlargements of the prostate render the passage of such rigid instruments a possible source of trauma. An x-ray film of the lower urinary tract will determine the presence or absence of stones in the bladder or prostate. The injection of the bladder with air or an opaque medium will betray the presence or absence of diverticula and the extent of trabeculation the prostatic obstruction has produced. The examiner's finger in the rectum, in most cases will reveal the type of enlargement and its gross extent. A soft rubber catheter will determine the amount of residual urine present. There thus remains little or nothing to be added from cystoscopy. The urologist who is dependent on the cystoscope to determine what method of treatment is best to employ for the relief of prostatic obstruction is apt to increase the obstruction by his instrumentation

so much that complete urinary retention frequently results. He is then faced with undertaking surgical measures in an area needlessly injured and infected and thus increasing the risk of postoperative febrile reaction, if not more serious complications. When residual urine is present, only trauma is necessary to add secondary infection, an unhappy prelude to any form of surgery. Probably in no condition has instrumentation been more painful and uselessly employed or yielded less worthwhile information than in routine cystoscopy of the elderly male with urinary obstruction the result of prostatic hypertrophy.

SUPPLEMENTARY INFORMATION

With the advent of intravenous urography, it seemed for a time that the need of instrumental examinations, particularly the passage of ureteral catheters, would be greatly curtailed. This has not proved to be the case. The unsuspected pathologic condition that has been revealed by the general use of intravenous pyelography has made evident the need for much supplementary information. This can be obtained only by the ureteral catheterization and the visual examination of the lower urinary tract. To attempt to diagnose and undertake treatment of a pathologic condition in the urinary tract simply by evidence obtained from intravenous urography is a responsibility that no wise or conscientious urologist much less a general practitioner, should care to assume. Unless all possible information from all possible sources is at hand, both diagnosis and treatment are of doubtful validity.

112 North Madison Avenue

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. BALLENGER, McDONALD AND
COLTMAN, DR. McKIM, SMITH AND RUSH
DR. HENLINE AND DR. BUMPUS

DR. MEREDITH F. CAMPBELL, New York. It was gratifying that Drs. Ballenger, McDonald and Coleman in their discussion of the sulfonamide treatment of gonorrhea of urethritis did not belabor us with considerations of the sulfonamide blood level. It was observed in the Urology Department of the College Clinic of New York University College of Medicine that practically all patients with gonococcal infection did as well on 2 Gm as on 4 Gm a day of a sulfonamide compound. Subsequent experience continues to bear this out. They emphasized the importance of the small external meatus in the genesis and perpetuation of a chronic urethral discharge, which may or may not be bacterial. A small meatus, with or without faulty sexual hygiene will engender prostatitis, the clinical manifestations of which usually cause the diagnosis of nongonorrheal or nonspecific urethritis to be made. I was especially pleased that the authors placed a satisfactory meatal caliber of the normal adult at 26 F rather than smaller. The abnormally small meatus in the young is generally so congenitally and in most instances is overlooked unless complicating ulceration with or without incrustation and scab formation and hematuria attracts clinical attention. Wide meatotomy and the maintenance of a wide open orifice rather than salves and ointments is the indicated treatment. Following meatotomy it is my practice periodically and progressively to dilate the incised orifice with steel sounds rather than to rely on domestic improvisations of the patient. Our experience in the treatment of well over a thousand enuretic children subscribes to the authors' statements regarding this condition. Granted that the syndrome commonly designated clinically as enuresis is a functional problem in 95 per cent of children is generally directed against the mother and in most instances responds to psychotherapy, gold stars and the like in all cases not responding in three to four months of intensive medical treatment or psychotherapy a thorough urologic examination should be carried out. About 1 in 7 of these children cannot empty his bladder completely.

intravenous therapy with arsenical compounds, gave support to the theory that pinta was a type of spirochetosis.

The strongly positive serologic reactions encountered led some clinicians to believe, despite the contention of Fox⁴ to the contrary, that pinta was related to both trambesia and syphilis. Several investigators found additional evidence indicating a relationship between pinta and syphilis. Thonnard-Neumann, Camacho, Moya and Brewster,⁵ and later Pardo-Castello and Ferrer⁶ and Saenz, Grau Triana and Alfonso Armenteros⁷ observed cardiovascular lesions such as aortitis, aneurysm, aortic regurgitation and enlargement of the heart. Saenz, Grau Triana and Alfonso Armenteros discovered changes in the spinal fluid resembling those associated with cerebrospinal syphilis (an increased content of globulin, a syphilitic colloidal gold curve and positive Wassermann, Kahn and McMichael reactions). Clinical manifestations of syphilis of the central nervous system were absent. In 1938 Grau Triana and Alfonso Armenteros discovered the causative spirochete in lymph from the cutaneous lesions, in the lymphatic glands and in the tissues. The discovery was confirmed two days later by Pardo-Castello. The organism was indistinguishable morphologically from the spirochete of trambesia and that of syphilis.

In 1939 all doubt as to the relationship of pinta to trambesia and to syphilis was dispelled when Leon y Blanco⁸ published the results of his classic and heroic experiments on pinta in Mexico and Cuba. Pardo-Castello translated the reports and summarized them.

The experiments were performed on four different groups of patients, the first of which included Leon y Blanco himself. He gave himself and 17 Mexican volunteers intracutaneous inoculations of material from Mexican patients with typical pinta. Four Cuban subjects in Havana were inoculated with material from Mexican and Cuban patients.

Leon y Blanco proved that the achromic stage of pinta, which to that time had been the only manifestation recognized, is in reality the tertiary or late dyschromic stage. He found that the initial lesion is always a closed papule that never ulcerates. It usually appears on the extremities, most often on the legs, but occasionally is found on the face or the neck. For several months this type of lesion remains the only manifestation of the disease and several may be present at once.

After five months or more signs of dissemination appear in the form of multiple macules or papules that grow and spread peripherally for several inches, just as do the initial lesions. In the course of several weeks circinate plaques are formed, the secondary lesions, which Leon y Blanco called pintids but which are popularly known in Mexico as empeines. These may be smooth or scaly. The initial lesions finally become part of the disseminated secondary manifestations and cannot be distinguished from them.

The lesions which usually are superficial are sometimes infiltrated, but they never ulcerate or produce a break in the epidermis. The earlier ones are faintly

pink, but they soon darken according to the amount of pigment and the congestion in the affected skin. In white patients the lesions are pink, red or brown, while in the dark races they are purple, blue, slate colored or black. Scaly lesions may have a dusty, ashen appearance, and the scales are usually adherent and powdery. When the scales are large the patches resemble the lesions of psoriasis, trichophytosis, lichen planus or eczema. Groups of pintids coalesce to form larger plaques.

In some cases the lesions involve only a small area, and in others they cover the greater part of the cutaneous surface. Usually, however, they are found on the extremities and bony prominences especially on areas not covered by clothing. After several months, when the pintids pass into the chronic stage, they tend to be symmetrically arranged especially on the hands and feet. Old lesions have a tendency to show slight central involution, indicated by a lighter color or even achromia. The border then appears darker and advances on the normal skin requiring several months or a year to reach a diameter of from 1 to 2 inches. They frequently have a well margined and sometimes polycyclic border.

According to Pardo-Castello and Ferrer⁶ the differentiation of pintids from the lesions of leprosy and other inflammatory dermatoses may be difficult. However, the presence of normal sensation for pain and temperature in pinta and the easy demonstration of *T. carateum* in the lesions distinguish the disease from leprosy.

During the secondary stage of the disease, which may last a year or longer, the Wassermann and Kahn reactions are positive in only 60 per cent of the cases. The general health is never affected. The spirochete is easily demonstrated by dark field examination in lymph extracted from the lesions. Discrete enlargement of the lymph nodes has been reported and spirochetes have been recovered from them. Saenz, Grau Triana and Alfonso Armenteros⁷ reported superficial enlargement of the lymph nodes in the inguinal region, of the epitrochlea and of the biceps muscle.

The secondary stage lasts from several months to more than a year. Then the lesions become dyschromic, producing the clinical picture of the late form of the disease so well known in Ecuador, Colombia, Cuba, Mexico and Venezuela. The lesions are symmetrically arranged usually on the extremities, and consist of alternating areas of depigmentation and hyperpigmentation. The resulting clinical picture is that of vitiligo. Cases in which there is symmetrical arrangement of dyschromic lesions on the face and trunk occur in all the countries mentioned except Cuba.

The pigmented lesions of the third stage are coffee color, slate blue or jet black according to the darkness of the normal skin. In white persons they are light brown. They may be localized on one extremity or on a hand and a foot on opposite sides. Follicular keratoses and areas of desquamation have been reported. The amount of desquamation varies in different persons and on different areas but the scales are usually branny and adherent. Atrophy of the skin in the achromic areas may occur in patients whose disease is of long duration.

Pardo-Castello and Ferrer⁶ reported involvement of the mucous membranes. One of their patients had a triangular area of hyperpigmentation on the dorsum of the tongue, and another had patches of stippled pigmentation on the inside of the cheeks and on the palate.

⁸ Leon y Blanco, F., cited by Pardo-Castello and Ferrer⁶.

It is in the late stage of the disease that the previously mentioned complications—hypertension, cardiovascular lesions and changes in the spinal fluid—are observed. Thonnard-Neumann, Camacho Moya and Brewster³ reported cardiovascular changes in 80 per cent, Saenz, Grau Trina and Alfonso Armenteros⁷ in 23.3 per cent and Pardo-Castello and Ferrer⁶ in 64.5 per cent of patients with pinta. Changes in the spinal fluid were observed by Saenz, Grau Trina and Alfonso Armenteros in 10 per cent and by Pardo-Castello and Ferrer in 52.1 per cent. Pardo-Castello and Ferrer⁶ observed 8 patients with hypertension in 5 of whom no aortic changes were demonstrable. The Wassermann and Kahn reactions of all the patients were strongly positive in this stage. Lymph from the affected areas, except those which are old, atrophic and burned out, is rich in spirochetes. The vitiligoid areas vary in color from milk white to ashen gray to yellowish white.

In the Cuban form the cutaneous lesions are not so regular or so prominent as in other forms. In most of the Cuban and in many of the Mexican patients the initial lesions and the early disseminated manifestations are slight and transient and may be overlooked. Dyschromic areas in which depigmentation alternates with slate blue hyperpigmentation are observed on the dorsal surfaces of the hands and feet, on the forearms and on the legs. The face, trunk, abdomen and thighs are usually free from lesions.

Diffuse or punctate palmar and plantar hyperkeratoses with or without fissures, which are characteristic of Cuban pinta, are absent in the Mexican form. Such hyperkeratoses never affect the dorsal surfaces of the hands and feet. They begin as slate blue hyperpigmented spots and simultaneously enlarge peripherally and increase in number. In time keratoses may entirely cover the palms and soles. According to Gonzalez Herrejon, dyschromic changes of the palms are rare in Mexican pinta. The terminal stage is represented by achromic vitiligoid areas. Symmetrical depigmented triangles on the flexor surfaces of the wrists, which are a common feature of Cuban pinta, also occur in Mexican pinta. Pardo-Castello expressed the opinion that the more limited character of the chronic form of Cuban pinta is undoubtedly the result of constitutional factors and not of differences in the etiologic agent.

Leon y Blanco's second group of patients consisted of 3 Mexicans known to have syphilis. He inoculated them intracutaneously with material taken from Mexicans with pinta and containing the causative spirochete. Numerous disseminated cutaneous lesions, or pintids, developed in all 3 subjects. Inoculation of another person with lymph from their lesions resulted in the development of pinta but not of syphilis. These experiments established the individuality of pinta as a type of spirochetosis and also proved that patients with active syphilis are susceptible to pinta.

The third group consisted of 3 patients who had had pinta but had been treated with and apparently cured by arsenical preparations administered intravenously. Intracutaneous inoculation with material containing *T. carateum* resulted in the development of an initial lesion but no disseminated lesions, or pintids, appeared. The fourth group, 5 patients with active late dyschromic lesions of pinta, were inoculated with similar material intracutaneously and were observed for forty-nine days but no initial lesion developed.

The last two experiments established that reinfection with *T. carateum* is only partially successful in the early stages of pinta, that patients with late dyschromic lesions cannot be reinfectd and that an attack of pinta confers immunity. By means of similar experiments carried out in Cuba, Leon y Blanco proved that Mexican and Cuban pinta are the same disease.

With regard to the mode of transmission of pinta, Pardo-Castello and Ferrer⁶ stated that infection probably results from local contact with affected persons, since experimental inoculations can be made through minute and superficial abrasions of the skin. When one recalls that Leon y Blanco found *T. carateum* in the sweat of the surface of the affected skin of his patients, it is not surprising that the disease should be spread by simple contact. No case has been reported in which pinta was of venereal origin.

Pardo-Castello and Ferrer stated that only 12 per cent of their Cuban patients were white persons, most of the remaining 88 per cent being Negroes. In Colombia, Mexico and Venezuela the majority of the patients were Indians or mestizos, the latter being the most frequent sufferers. In Mexico children were frequently affected, but Pardo-Castello and Ferrer did not find any in whom the disease was of congenital origin. Their youngest Cuban patient was 23 years old, but they stated that their colleagues had had patients who were only 10.

The histopathologic changes of the late lesions of pinta, which are the best known and which in the main were shown by our sections, have been described by Ochotorena,⁹ Gonzalez Herrejon and Pallares¹⁰ and Pardo-Castello and Ferrer⁶. They consist of atrophy of the epidermis, absence of pigment in the basal layer, huge accumulations of melanophores in the upper part of the corium, alternate or continuous bandlike infiltration in the papillary and subpapillary layers and, when there is hyperkeratosis, accumulation of horny material in the atrophied epidermis. Extracellular grams of pigment may be present in and between the cells of the infiltrate. In the vitiligoid patches there are atrophy of the epidermis, absence of the papillae, complete absence of pigment and sclerosis of the connective tissue. These changes represent the final atrophic and cicatricial stage of cutaneous pinta.

The treatment of pinta is similar to the treatment of frambesia and of syphilis. Gratz¹¹ of Colombia was the first to call attention to the use of compounds of mercury and of arsenic for pinta. Arsenical preparations administered intravenously and bismuth and mercury compounds administered intramuscularly are specific. However, as in the treatment of frambesia and of syphilis, the arsenical compounds are the more rapidly effective. Mexican and Cuban dermatologists have found that the effect of treatment on the serologic reactions was not so good as the rapid involution of the cutaneous lesions had led them to expect. The Wassermann and Kahn reactions of many of their patients remained persistently positive in spite of the most intensive and prolonged treatment. The serologic reactions of some patients became negative but only slowly. Our limited experience with pinta in 3 patients coincides with the foregoing observations.

9 Ochotorena I. Estudios histológicos y micológicos acerca del mal del pinto. Mexico: Departamento de Salubridad, 1929.

10 Gonzalez Herrejon S and Pallares M. cited by Pardo-Castello and Ferrer⁶.

11 Gratz R M. cited by Holcomb R C. Pinta a Treponemato: A Review of the Literature. U S Nav M Bull 40: 517 (July) 1942.

The pathogenicity of *T. carateum*, according to Pardo-Castello, is much less than that of *Treponema pallidum*, and pinta is therefore much less dangerous than syphilis. However, because of the persistence of positive serologic reactions in the absence of active lesions and especially because of the high incidence of cardiovascular complications, the treatment of pinta should be continued until the serologic reactions are negative. When these reactions remain positive in spite of intense and prolonged therapy with compounds of arsenic and of the heavy metals, fever therapy or treatment with nonspecific proteins followed by therapy with heavy metals is worthy of consideration.

Pardo-Castello and his associates studied the histories and examined the histopathologic sections and photographs of our patients and agreed that in cases 2 and 3 the disease was exactly the same as the Cuban form of pinta. In case 1 the type was that seen in Mexico, Colombia, Ecuador and Venezuela. Unfortunately, because of an oversight, the diffuse bluish areas on the inner sides of the thighs, the slate colored hyperpigmentation on the cheeks and the mottled areas on the flexor surfaces of the elbows and the lower thirds of the arms in case 1 were not photographed in detail. By the time the error was discovered, the lesions had been cured by intravenous injections of an arsenic preparation and intramuscular injections of a bismuth

derivative in the vicinity of the plaques. The surrounding skin had retained its normal light brown sheen.

The patient stated that in the areas of depigmentation on her body there had been, years before, hyperpigmented lesions similar to those on the malar eminences.

The skin on the inner sides of the breasts, on the submammary and lower sternal areas, on the entire abdomen, on the flexor and lateral surfaces of the thighs and on the lower lumbar and sacral regions presented a strikingly mottled appearance, the result of contrast between large vitiligo areas and normal light brown skin. Pinhead sized to pea sized vitiligo areas were present over the lateral surfaces of the neck and the entire dorsal surface of the trunk. The flexor surface of the lower third of each upper arm and of the upper third of each forearm had a finely reticulated appearance due to the presence of partially depigmented, faintly outlined vitiligo areas the same size as those on the neck and the trunk and peculiar, sharply outlined and slightly elevated bluish black pinhead sized areas on a background of normal skin. There were a few isolated partially or completely depigmented lesions ranging in size from that of a pea to that of a dime (18 mm) on the dorsal surfaces of the hands, on the lateral and flexor surfaces of the legs and on the lateral surfaces of the ankle joints but not on the dorsal surfaces of the feet. The palms and soles were free from dyschromic changes.

An area the color of diluted laundry bluing and level with the skin was present on the inner side of each thigh from the genitocrural region almost to the knee. The hyperpigmentation extended around to the extensor surface of the thigh for several inches. Two intensely pruritic black stippled lesions were situated midway between the scapulas. They were elevated about 3 mm and were the size and shape of lima beans, resembling the lesions of psoriasis.

The results of additional antisyphilitic therapy were striking. Two months after treatment with neoarsphenamine had been instituted, the hyperpigmentation on the thighs as well as that on the malar eminences had disappeared. An additional three months of combined treatment with bismuth and arsenic caused complete involution of the psoriasiform lesions and the reticulated areas on the arms. Before treatment was given in our clinic dark field examination, impregnation of the tissues with silver, examination of stained smear preparations and inoculation experiments on animals all failed to reveal the presence of spirochetes. Study of the spinal fluid and cardiovascular and neurologic examinations revealed no abnormalities.

The Wassermann and Kahn reactions of the blood were both strongly positive Dec 17, 1940 and April 7, 1941. Sept 15, 1941 and April 7, 1942 the Wassermann reaction of the blood was negative, but the Kahn reaction was still strongly positive.

Biopsy of a depigmented area on a hip revealed the following microscopic changes. The epidermis showed pronounced hyperkeratosis. The rete pegs were reduced to small protrusions in some areas and were absent entirely in others. In the papillary part of the corium was a band of perivascular round cell infiltration. The blood vessels were dilated, the intima in some being edematous and in others proliferated to such an extent that the lumens were almost occluded. Except for a few melanoblasts, pigment was absent in the basal layer. A few chromatophores were visible in the subpapillary layer. Biopsy of one of the hyperpigmented lesions in the interscapular region revealed hyperkeratosis of the stratum corneum. The rete was slightly atrophic, the rete pegs being reduced in many places to small protrusions. Moderate perivascular round cell infiltration was visible in the papillary portion of the corium. The lymph spaces and the blood vessels were moderately dilated. The intima of the vessels showed slight edema, and in many capillaries proliferation of the intima was of a degree leading to almost complete occlusion. Pigment was present in the basal cell layer of the rete and in the stratum spinosum. Chromatophores and granules of free pigment were present in the subpapillary layer of the corium.

CASE 2—An obese Negro woman aged 51 entered the dermatologic department of Michael Reese Hospital on May 12, 1940 complaining of pains in the arms, hands and knees, edema of the ankles, dyspnea on exertion and severe pruritus of the palms and of the dorsal surfaces of the hands, including the fingers.

Fig. 1 (case 1)—A vitiligo lesions. B with superimposed light brown areas of normal skin. C on the right side of the patient's body.

preparation. At the time my associates and I performed our inoculation experiments on animals we did not yet know that *T. carateum* is extremely susceptible to the action of the compounds of arsenic and of bismuth. It is impossible to demonstrate it in patients twenty-four hours after one injection of a bismuth or an arsenical compound.

REPORT OF CASES

CASE 1—A well nourished woman of 51 entered the dermatologic department of Michael Reese Hospital on Dec 17, 1940 complaining of generalized pruritus and "white spots" on the skin.

She was born in St. Catharines, Ont., of mixed parentage, her father was Cherokee Indian and French and her mother Blackhawk Indian and Negro. At the age of 3 months she was taken to Pittsburgh, where she lived until 1939, when she moved to Chicago.

During the preceding six months she had been given two courses of treatment with bismuth salicylate, although a history of syphilitic infection had not been obtained.

At the time of admission to our clinic, in addition to the cutaneous lesions, the patient was suffering from severe asthma. There was no adenopathy.

On the malar eminences were cutaneous lesions in the form of peculiar bluish black, fairly sharply margined plaques about the size of a half-dollar (30 mm) and elevated about 2 mm. Numerous pinhead sized lesions of the same color and elevation but more sharply delimited were present in the imme-

The patient was born in Louisiana and lived there until 1939, when she moved to Chicago. In the preceding seven years she had had seven abortions each of which occurred spontaneously in the fourth month. She had received one course of treatment with neotarsphenamine and bismuth salicylate before entering our clinic.

In addition to obesity and the cutaneous lesions she had advanced dental caries and infectious arthritis. There was no adenopathy.

Fig 2 (case 2)—Deep black hyperpigmented plaque characteristic of *pinta*. A extending from the dorsal surface of the left wrist joint to involve half of the dorsal surface of the forearm. Depigmentation of the entire dorsal surface of the left hand and parts of the dorsal surface of the thumb and fifth finger of the right hand. B continuation of the plaque on the flexor surface of the left forearm. Characteristic triangular areas of leukoderma on the flexor surfaces of the wrists.

The skin on the dorsal surfaces of the left hand, including the fingers, showed depigmentation which extended several inches above the wrist joint. Rests of normal black skin of various sizes and irregular outline were superimposed on the vitiligo areas. These areas were rough and resembled the surface of a fine mesh nutmeg grater.

The depigmented area on the back of the left hand was sharply demarcated above the wrist joint by the lower border of a black plaque, 3 mm thick, which extended from the dorsal surface around to the flexor surface of the forearm, to end several inches above the wrist in a vitiligo area shaped like an inverted V. A deep black, sharply outlined plaque 3 mm thick extended upward from the depigmented area near the dorsal surface of the wrist, involved half of the extensor surface of the left forearm and wound around the middle of the forearm to end in a similar plaque which involved half of the flexor surface and was bounded distally by the V shaped vitiligo area at the wrist.

The lesions on the palms were of two types, hyperkeratotic and macular. The hyperkeratotic lesions were black, slightly scaly, elevated and almost the size of a dime. The macular lesions were deep brown, about the size of a pea and sharply outlined. A partially depigmented area was present on the medial surface of the fifth finger of the right hand at the first metacarpophalangeal articulation. The lesion extended laterally and proximally for about an inch and wound around to the flexor surface of the forearm to end at the wrist in a vitiligo area shaped like an inverted V. An identical area was present on the dorsal surface of the thumb at the first phalangeal articulation.

The patient stated that all of the depigmented areas had been preceded by plaques of the same color and thickness as those on the left forearm. These had been present for many years. Hyperpigmentation had been noticed first in 1919 but depigmentation had not appeared until 1939.

When the patient was admitted to the clinic the Wassermann and Kahn reactions of the blood were strongly positive and they remained strongly positive until Dec 15, 1942 in spite of continuous treatment with arsenical compounds given intravenously and bismuth compounds given intramuscularly. After that date they were consistently negative.

The cutaneous response to therapy was more rapid. The pruritus of the hands disappeared after a few injections of neotarsphenamine. After six weeks of therapy the roughness of the dorsal surfaces of the hands was replaced by superficial

atrophy. The black plaques on the left arm disappeared after three months of therapy and the hyperkeratotic and the macular lesions of the palms after two months.

Study of the spinal fluid and neurologic and cardiovascular examinations failed to reveal any pathologic changes. Ophthalmologic examination revealed corneal opacities, which were especially pronounced in the outer segments. Spirochetes could not be demonstrated by dark field examination, impregnation of the tissues with silver, study of stained smear preparations or inoculation experiments on animals. (The testes of rabbits were inoculated with tissue from the hyperpigmented and the depigmented lesions.)

Biopsy of a totally depigmented area at the left hypothenar eminence revealed a hyperkeratotic and definitely atrophic epidermis entirely without pigment. The pathologic changes in the corium were restricted to the pars papillaris and consisted of dilatation of the capillaries and lymph spaces, edema of the connective tissue and round cell infiltration of perivascular distribution. The reticular portion of the corium showed slight edema, and round cells were distributed between the connective tissue bundles. The capillaries and the larger and smaller vessels showed edema and desquamation of the intima. In some of the vessels intimal proliferation had advanced to such a degree that they were almost occluded.

Biopsy of a hyperpigmented patch on the flexor surface of the left forearm revealed pronounced hyperkeratosis with preservation of the stratum granulosum. The rete malpighii showed progressive atrophy, which in some areas was far advanced. Considerable round cell infiltration was present in the subpapillary portion of the corium, which also showed advanced edema and destruction of the connective tissue bundles. The lymph spaces and blood vessels were dilated and edematous, and there was desquamation of the intima. The vessels in the reticular portion of the corium showed intimal proliferation of a degree sufficient to bring about almost complete occlusion of the lumens. The basal layer of the epidermis and the papillary portion of the corium were virtually packed with pigment in melanoblasts and chromatophores and with coarse granules lying between the connective tissue bundles.

CASE 3—An obese Negro aged 50 entered the dermatologic clinic of the Michael Reese Hospital on May 2, 1939, referred

Fig 3 (case 3)—A vitiligo lesions on the dorsal surface of the right hand including the fingers. B dyschromia of the palm and volar surfaces of the fingers of the right hand. Characteristic triangular area of leukoderma at the wrist. C dorsolateral view of the right hand showing continuation of the vitiligo area to the forearm to end on the flexor surface in the characteristic triangular area of leukoderma.

from the surgical department because of positive serologic reactions and headache and vertigo of six months duration.

The patient was born in Alabama and lived there until 1939 when he moved to Chicago. There was no history of syphilitic infection although the Wassermann and Kahn reactions of the blood were both strongly positive on a number of occasions. Adenopathy was not present.

The patient was referred for examination to the medical department, which reported enlargement of the aorta, accentuation of the second aortic sound and a systolic murmur at the apex. The blood pressure was 188 systolic and 114 diastolic. Neurologic examination and examination of the spinal fluid revealed no evidence of disease of the central nervous system.

On May 2 the clinician who first saw the patient observed a black, sharply outlined dollar sized (38 mm) hyperpigmented patch 5 mm thick on the flexor surface of the right wrist extending 1 cm into the palm. There was a juxta-articular node on the dorsal surface of the second phalangeal articulation of the fifth finger of the same hand. A second node was present in the suprapatellar region of the right leg. The patient stated that these nodes had been present for six years.

The patient had already received three courses of treatment with bismuth subcitrate and by the time we saw him on May 9, 1940 the hyperpigmented patch at the wrist and the juxta-articular nodes had disappeared.

The dorsal surfaces of the right hand including the fingers, had a mottled appearance resulting from contrast between irregularly outlined vitiloid patches and normal black skin. The depigmentation extended from the dorsal surface of the metacarpophalangeal articulation of the thumb and from the dorsomedial surface of the forearm to end in a V-shaped vitiloid area terminating several inches above the wrist joint.

The palm was studded with coal black sharply outlined, hyperkeratotic slightly scaly lesions about the size of a pea, with irregularly outlined depigmented areas and with irregularly outlined dark brown lesions ranging in size from that of a dime to that of a pea. When first seen the depigmented lesions on the dorsal surfaces of the hand including the fingers, were of a peculiar pinkish color and so rough that they resembled a fine mesh nutmeg grater.

The patient in 1927 had first noticed black hyperpigmented areas on the fingers and hand at the sites where the vitiloid areas later appeared. The hyperpigmented patch on the flexor surface of the forearm was also present at that time. Depigmentation appeared in 1930. The hyperkeratotic lesions disappeared after three months of combined therapy with compounds of arsenic and bismuth, and the depigmented areas became perfectly smooth, ivory white and atrophic. On Nov. 20, 1941, the last time the patient visited the clinic the Wassermann and Kahn reactions of the blood were still strongly positive.

Biopsy of a depigmented area on the flexor surface of the right wrist revealed pronounced hyperkeratosis, atrophy of the rete, absence of pigment in the epidermis and round cell infiltration which extended to the basal cell layer throughout the section and was especially prominent in the papillary layer of the corium. The small capillaries in the infiltrated portion of the papillary layer were dilated, and their intima showed desquamation. The intima of the larger capillaries in the papillary layer and of the vessels throughout the reticular layer of the corium showed proliferative changes. In many instances these were so extensive that the lumens of some vessels were materially narrowed and of others occluded.

On Aug. 8, 1942 the patient was admitted to the medical service of Michael Reese Hospital acutely ill. The clinical diagnosis was arteriosclerotic heart disease, malignant nephrosclerosis and uremia, and he died on August 24. Dr. Otto Saphir, who performed the autopsy, failed to find any evidence of syphilis but reported general arteriosclerosis, old pyelonephritis in arteriosclerotic kidneys, hypertrophy and dilatation of the heart, chronic passive hyperemia of the lungs, liver, kidneys and spleen, bilateral bronchopneumonia of the lower lobes, a small aneurysm of the right coronary artery and old bilateral fibrous pleuritis.

All 3 patients maintained that they had never had sexual relations or shared living quarters with persons who had lived in the tropics or who had had lesions resembling theirs.

THE CONTROL OF AN OUTBREAK OF BACILLARY DYSENTERY WITH SULFONAMIDES

HENRY M. EISENOFF, MD

Attending Pediatrician, Ichabod Hospital, Medical Director, Israel Orphan Asylum

AND

HYMAN GOLDSTEIN, MD

Assistant Medical Director, Israel Orphan Asylum
NEW YORK

Bacillary dysentery continues to be a problem in crowded institutions, army camps and orphanages. The difficulty of control has been pointed out by many authors.¹ In former years treatment of the cases was purely symptomatic and control of the infection could be obtained only by isolation and quarantine or by permitting the outbreak to run its course after it had attacked a large percentage of the susceptible. Since the introduction of the sulfonamides, favorable reports of treatment of cases of bacillary dysentery with these drugs have appeared in the literature.² Of late the less soluble drugs, particularly sulfaguanidine and succinylsulfathiazole, have had a considerable vogue. Theo-

retically there should be an advantage in the use of these drugs, since the concentration of the drug in the intestinal tract is higher than with the more readily absorbable ones.

OUTBREAK

We had an opportunity recently to test the value of the sulfonamides in the control of an outbreak of bacillary dysentery, Sonne type. The outbreak occurred in an orphan asylum housed in a well constructed five story building. There was a total of 145 white children being cared for in the building at the time of the investigation, and these were divided into four groups, one each on the second, third, fourth and fifth floors. While the children are kept in their respective quarters they visit one another, eat together in the dining room and mingle at play and school. Some of the children

From the Israel Orphan Asylum, New York City. Dr. Morris Greenberg, epidemiologist of the New York City Department of Health, gave assistance and counsel. All the laboratory work was performed for us in the enteric fever laboratory of the New York City Department of Health, and Miss Carolyn Oldenbush rendered assistance. Miss Charlotte Rosenzweig, nurse in charge at the Israel Orphan Asylum was cooperative and helpful.

receive instruction in the building, others, the older ones, attend a public school across the street. There were no cases of diarrhea or dysentery in this public school.

On Dec 16 1942 S H a boy aged 11 of the fourth floor group who had been in the institution since 1939 became ill with diarrhea which persisted for about three days. No cultures of his stool were made. On Jan 4 1943 this child again became ill with vomiting fever and diarrhea. A stool specimen was submitted to a private laboratory on January 8 and was reported as positive for dysentery bacilli.

On January 24 children on the second floor became ill with symptoms of vomiting fever and diarrhea. They had been in the institution for at least three months. Other children on this floor developed similar symptoms and by January 13 all the 24 children on this floor had become ill. The disease spread to the other floors. On January 2 a case occurred on the

Cases by dates of onset and location in building

third floor and 3 other children later became ill on this floor. From January 4 to February 2, 9 cases occurred on the fourth floor, and from January 15 to January 28 12 cases developed on the fifth floor. A total of 50 children became ill between January 2 and February 4. The onsets are shown in the chart.

An investigation was begun toward the end of January. All new admissions were discontinued. The sick children were isolated, and stool specimens were obtained from all children in the institution as well as from all adults employed there. At least 3 specimens were cultured from each child. Those with positive specimens were not released until three successive specimens taken not less than forty-eight hours apart were reported as negative by the laboratory. A final survey was made of all the children by cultures inoculated directly from a rectal smear, before the institution was permitted to reopen.

Table 1 shows the distribution of the cases in the institution, as well as the results of the culture survey. It will be noted from the table that there were 33 boys and 17 girls affected and that 33 of the 50 children or 66 per cent had *Bacterium sonnei* in their stools.

Bacteriologic Examination—Stool specimens were received in the laboratory in paper containers on the same morning that they were passed, usually within one to three hours. They were plated with a heavy inoculum on SS agar, and streakings were also made on plates of MacConkey and bismuth sulfite. Bismuth

TABLE 2—Treatment of Bacteriologically Positive Cases and Carriers According to Drug Administered

Floor	Sulfa thiazole	Sulfa diazine	Sulfa guanidine	Succinyl sulfa thiazole	Total

Third		11	9		20
Fourth	11	2	9	6	28
Fifth			4	21	25
Total	21	13	22	27	83

sulfite plates were examined after incubation for forty-eight hours. MacConkey and SS agar plates were examined after incubation for twenty to twenty-four hours and suspected colonies fished on to Krumwiede's triple sugar medium and incubated for sixteen to twenty hours. Colonies giving *Shigella* reactions were fished and tested with type specific antisera. Inoculations into sugar tubes were made only at the beginning of the study. Later cultures were classified by means of agglutination reactions with type specific antisera only.

A total of 715 cultures were made from the 145 children. None of the specimens from the adults were positive, and they are therefore omitted from consideration in this study. Specimens from 83 children were positive for *B. sonnei*. Of these, 33 were from children who were ill or had recently recovered, and 50 were from symptomless carriers. Their distribution in the building is shown in table 1.

An attempt was made at first to isolate all children with positive stools as they were discovered. However, facilities were lacking for the isolation of so many and it was therefore decided to use the sulfonamides in an attempt to control the outbreak. Four of the sulfonamides were employed: sulfathiazole and sulfa-

TABLE 3—Bacteriologically Positive Children Not Cleared After One Course of Treatment

diazine in doses of 1 grain per pound of body weight and sulfaguanidine and succinylsulfathiazole in doses of 2 grains per pound of body weight. The drugs were administered to all children with positive stools. No selection was made in the children treated with the different sulfonamides. The nurse was instructed to give the four drugs in rotation to numerically equal groups of patients. This was fairly well carried out except that sulfadiazine was given to a smaller than

average group, as is indicated in table 2. The children were kept on the drugs for an average of four days. Some received it for only three days and others for as long as six days. Of the 83 cases and carriers all but 8 failed to show B sooner in their stools following treatment. Of the 8 whose stools were positive after treatment 3 had received sulfathiazole, 3 sulfaguandine and 2 succinylsulfathiazole. All were again treated with a different sulfonamide, 6 cleared up while 2 required a third course of treatment (table 3).

Clinical Findings—The cases were mild and no deaths occurred. Diarrhea lasted between two and four days. The stools contained mucus and blood. Temperatures in most cases ranged between 100 and 101 F., but in a few cases the temperature at onset was between 103 and 104 F. Abdominal cramps and vomiting occurred during the first twenty-four hours only. Blood counts were done on all patients and varied between 7,500 and 10,000 white blood cells per cubic millimeter. The polymorphonuclear leukocytes ranged between 65 and 72 per cent. Urine specimens were all normal.

All children were followed with frequent blood counts and urine examinations while receiving the drugs. No blood was found in any of the urinary specimens and no significant reductions in the number of red and white blood cells or in the percentage of granular blood cells. Two children developed a red macular rash, one after four days of treatment with sulfathiazole and the other after three days of sulfadiazine administration. The rash disappeared within twenty-four hours after the drug was discontinued.

COMMENT

The sulfonamides appeared to be quite effective in the control of the outbreak. In the dosages and for the periods given no advantages could be claimed for one over the other of the four drugs used. As noted, sulfathiazole and sulfaguandine failed in 3 cases, each used respectively for six, four and four consecutive days, and succinylsulfathiazole failed in 2 cases in which it was given for four days. Sulfadiazine failed in 2 cases in which it was substituted for a period of three days for another drug which had failed (table 3).

An interesting feature of the bacteriologic examinations was the total inhibition of growth of all intestinal organisms on the mediums used as a result of the administration of the sulfonamides. This occurred in 80 per cent of all children treated with sulfathiazole, 70 per cent of those treated with sulfadiazine, 63 per cent of those treated with succinylsulfathiazole and 36 per cent of all treated with sulfaguandine. We are unable to say how soon after administration of the drug growth was inhibited or how long the inhibition lasted, since we did not take daily cultures. Some idea may be obtained, however, from the following examples:

1 Five children had positive stool cultures on February 2. Sulfathiazole was administered from February 4 to February 10. Stool cultures on February 8, 11 and 15 gave no growth. On February 24 stool cultures gave growths of *Escherichia coli*.

2 A child's stool was positive on February 5. He was treated with sulfadiazine from February 7 to February 10. Stool cultures on February 11 and 15 gave no growth. Stool culture on February 24 gave a growth of *E. coli*.

3 A positive culture was obtained from a child's stool on February 4. He was treated with succinylsulfathiazole from February 6 to February 10. On February 11 the culture of the stool gave no growth. On February 15 there was a growth of *E. coli*.

4 A child's stool was positive on February 22. She received sulfaguandine from February 24 to February 27. Stool cultures on March 1 and March 8 gave no growth. On March 10 a stool culture gave a growth of *E. coli*.

SUMMARY

1 An outbreak of Sonne dysentery involving 50 children occurred in an orphanage with a total census of 145. Bacteriologic survey disclosed 83 children with positive stool cultures.

2 The administration of sulfathiazole and sulfadiazine in doses of 1 grain and sulfaguandine and succinylsulfathiazole in doses of 2 grains per pound of body weight for an average of four days cleared 90 per cent of the children with positive stools. The remaining 10 per cent were cleared with one or two additional courses of treatment.

3 The administration of the drugs caused complete inhibition of growth of intestinal bacteria for a time in 80 per cent of all children treated with sulfathiazole, 70 per cent of those treated with sulfadiazine, 63 per cent of those treated with succinylsulfathiazole and 37 per cent of all treated with sulfaguandine.

Clinical Notes, Suggestions and New Instruments

COLD AUTOHEMAGGLUTININS FOLLOWING ATYPICAL PNEUMONIA PRODUCING THE CLINICAL PICTURE OF ACROCYANOSIS

MAJOR FERDINAND C. HELWIG, MEDICAL CORPS,
ARMY OF THE UNITED STATES

AND

LIEUTENANT EDWARD D. FREIS, MEDICAL CORPS,
ARMY OF THE UNITED STATES

The phenomenon of autoagglutination and autohemolysis has often been described in paroxysmal hemoglobinuria, which is sometimes encountered in congenital syphilis. In 1937 McCombs and McElroy¹ in a review of the available literature reported that autoagglutination had been observed in hemolytic icterus, trypanosomiasis, severe anemias and liver disease, occasionally in pneumonia and also in apparently normal persons. It has likewise been reported in cases of hemolytic anemia associated with sulfanilamide therapy² and acute hemolytic anemia due to lead poisoning.³ Wiener⁴ in his recently revised book on "Blood Groups and Transfusions" expressed the thought that the phenomenon must not be too rare because he himself had observed at least a dozen instances of autoagglutination occurring at room temperature.

In February 1943 Peterson, Ham and Finland⁵ reported finding a high incidence of cold agglutinins (autohemagglutinins) which appeared at low temperatures in the blood serum of patients with primary atypical pneumonia. In this report they suggested that the demonstration of cold agglutinins might possibly serve as a useful test for such atypical pneumonias.

Since atypical pneumonia has been prevalent in the armed forces during the past winter and, owing to the fact that we

have recently observed a striking instance in which autoagglutinins were active even at room temperature and produced vascular changes suggesting the clinical picture of acrocyanosis, it seemed worth while to report the following case

REPORT OF CASE

Corporal F., aged 38, was seen in the outpatient clinic of the Station Hospital because his barrack mates observed that his nose, ears, and hands were a deep purple (fig 1). He himself discovered that this phenomenon occurred only after he was exposed to cold.

He had suffered with a respiratory infection in March 1943, at which time a large number of patients with atypical pneumonia were being hospitalized at this air base. He was quite sick for about three days with cough and fever and did not recover from the cough and generalized malaise for about two weeks. The vascular phenomenon previously mentioned appeared for the first time, to his knowledge, about one month after the original onset of his symptoms. This soldier is much above the average in intelligence, and his statement, therefore, that this was the first time he had ever noted this condition

Fig 1—Patient after exposure to cold showing cyanotic discoloration of face and outer edge of auricular cartilage

seemed credible. No other member of his family was similarly affected. Prior to entering the armed services he was an accountant, and his military duties have been entirely clerical.

The clinical picture of acrocyanosis could be reproduced at will by exposing him to cold. After he returned to room temperature about fifteen minutes was required for the abnormal discoloration to disappear.

Capillaroscopy was made of the nailfolds of the patient's fingers. It was found that the capillaries reacted more or less normally to considerable variations in temperature, except for moderate ballooning of the summit of the loops when the hand was cyanotic. Not all capillaries in the field showed the latter phenomenon, and it was interpreted as being due to reversible intravascular autoagglutination. Thermocouple readings of hand skin temperatures before, during and after chilling varied but slightly from similar readings on normal controls. When an attempt was made to do a routine red cell count on the patient with the diluting fluid at room temperature, prompt agglutination of massive character took place in the hemocytometer pipet. However, when the diluting fluid was warmed a little above body temperature the agglutination was found to be completely reversible and a smooth even suspension of red

cells was obtained. Moreover, prompt agglutination could be produced again and again in hanging drop suspensions by repeated warming and chilling. The patient's blood was of group O. When the serum was separated from the clot it had the property of agglutinating not only the patient's own washed red cells but also the washed cells of normal group O

Fig 2—Section under high power magnification showing patient's washed red cells and serum after warming. Hanging drop preparation. No agglutination.

persons (figs 2, 3 and 4). After repeated chilling of the patient on numerous occasions, no hemoglobin was found at any time in his urine. Furthermore, the "acid hemolysis test" for exclusion of paroxysmal hemoglobinuria was entirely negative. The complete "acid hemolysis test" as described by Ham was carried out with the patient's red cells and the red cells of a known normal control with identical results.

Protein determinations showed a total serum protein of 6.4 per cent, albumin 4.9 per cent and globulin 1.5 per cent. The autoagglutinins were readily absorbable by the patient's own red cells and by red cells of normal group O persons. The autoagglutinins were active in dilutions up to 1:5,000. Moreover, these autoagglutinins could be recovered in saline solution from the washed agglutinated red cell masses and were found to be active again for group O red cells.

A careful physical examination and other laboratory studies for liver diseases, syphilis and other conditions in which cold agglutinins have previously been described were entirely negative. His blood picture was normal, and the only blood abnor-

Fig 3—Section under high power magnification showing agglutination of patient's washed red cells by his own serum after cooling. Hanging drop preparation.

malities that we could discover were the presence of these so-called cold autohemagglutinins, which were present even at room temperature, and an extraordinary rapid sedimentation rate when the cell suspension was placed in the ice box, whereas the rate was normal when the suspensions were warmed.

COMMENT AND CONCLUSIONS

We believe that when the patient was chilled the autohemagglutinins in his blood serum produced reversible intravascular agglutination. We further believe that this intravascular agglutination rather than an underlying structural or neurologic vascular disease produced the clinical picture of acrocyanosis.

Although cases exhibiting Raynaud-like phenomena associated with reversible autohemagglutination and paroxysmal hemoglobinuria have been described by McCombs and McElroy,¹ by Ernst and Gardner,² by Wiener,³ and by others, our case is unique in that there is no associated paroxysmal hemoglobinuria, a negative Donath-Landsteiner test and a negative Ham test for acid hemolysis. Davidsohn⁴ studied a patient with a condition resembling Raynaud's disease whose serum agglutinated her own cells at ice box temperature and at 22 C. Davidsohn does not mention whether this patient had paroxysmal hemoglobinuria or a positive Donath-Landsteiner test; unfortunately we have been unable to obtain any further information on this point. Peterson, Ham and Finland⁵ mentioned phlebotrombosis and pulmonary emboli complicating a few of their

FIG. 4—Section under high power magnification demonstrating agglutination with patient's serum and washed red cells of a normal person of the same blood type. Chilled hanging drop preparation.

cases of virus pneumonia associated with autohemagglutinins but they noted no examples of vascular phenomena similar to those in this case.

With the possible exception of the case reported by Davidsohn,⁴ the clinical picture of acrocyanosis has not to our knowledge been described before in connection with the isolated phenomenon of autohemagglutinins without autohemolysins. It may be that, with the higher incidence of atypical pneumonia producing autohemagglutinins, more cases will be observed. In conclusion, one cannot help but wonder whether one of the reasons for the wide variation in the descriptions of the underlying structural, pathologic, vascular changes recorded for acrocyanosis might not have had as their basis the fact that no true underlying pathologic condition existed aside from the possible presence of autohemagglutinins, which had not been observed or whose presence had not been properly interpreted. Moreover, the possible hazard in using convalescent blood, plasma or serum from persons who have recovered from atypical pneumonia should be in mind.

THE RITHE OF ACUTE PLEURITIC PAIN BY INTERCOSTAL NERVE BLOCK

HARRY J. PRICE, M.D., ATLANTA, GA

Pain of pleural origin causes the physician great concern in the treatment of pneumothorax and pulmonary infarction. It is often persistent, agonizing and exhausting. The rapid, shallow respiration which results from it does not aerate the lungs sufficiently and may promote atelectasis. Furthermore, it is the pain itself which brings the patient to the physician. Rapid relief of this pain gives the patient great confidence in the doctor. The variety of procedures suggested for the relief of pleural pain has emphasized the obstinacy of the problem. Counterirritation, adhesive strapping, the use of opiates, artificial pneumothorax and local injection of the pleura and subcutaneous tissues with procaine hydrochloride each has had its advocates.

My purpose in this report is to describe a procedure of relieving pleural pain by inducing intercostal nerve block with procaine hydrochloride. This method is simple and effective, often producing permanent relief of the pleural pain associated with pneumothorax. It allows relatively free motion of the thoracic wall and so favors adequate aeration of the lungs, affording protection against the complication of atelectasis. Drainage of the involved area of the lung is promoted, for coughing is rendered nearly painless. This is an added advantage in the occasional patient from whom it is difficult to secure a specimen of sputum. Cumbersome chest binders and adhesive tape are avoided.

METHOD

The nerves to be injected are those corresponding to the intercostal spaces over which definite tenderness can be elicited by slight pressure. The injection is made most conveniently in the posterior axillary line or anterior to this. However, in instances in which the hyperesthesia is located more posteriorly, injection can be made in the midscapular line. A procaine hydrochloride wheal is first made in the overlying skin. A 20 to 21 gage needle is then introduced through the anesthetized area of skin until contact is made with the outer border of the rib immediately above the selected space. The periosteum is anesthetized with a few minims of procaine hydrochloride after which the needle point is carried down to the inferior margin of the rib, where it falls into the groove occupied by the intercostal nerve and vessels. At this point traction is exerted on the plunger until the operator is certain that the needle has not entered a vessel. If no blood is drawn, the nerve is then infiltrated with 2 cc of a 1 per cent solution of procaine hydrochloride.

REPORT OF CASES

CASE 1—A white man aged 38 was admitted to the hospital with pneumococcal pneumonia of five days duration. A sharp, radiating pain had been present in the right lower quadrant of the chest for seventy-two hours. There was a pronounced increase in the respiratory rate as well as an inability to cough deeply. Infiltration of the fourth, fifth and sixth right intercostal nerves gave prompt and complete relief of pain without recurrence. Shortly after the injection was completed the patient fell asleep, this being his first rest since the onset of the pain.

CASE 2—A white man aged 60 with pneumonia involving the lower lobe of the right lung and associated severe pleuritic pain had the fifth and sixth right intercostal nerves blocked. There was cessation of pain with permanent relief and the patient was able to sleep.

CASE 3—A white man aged 66 with perforated peptic ulcer and right subdiaphragmatic abscess complicated by pneumonia involving the lower lobe of the right lung had severe pleural pain over the right lower lateral and anterior thoracic wall. There were hyperesthesia and muscular spasm over the right upper abdominal quadrant and pain on respiration in this region. Intercostal block of the lower six thoracic nerves on the right promptly relieved the thoracic pain and the abdominal pain that was produced by respiration, but abdominal tenderness and spasm persisted.

From the Medical Service of the Grady Hospital and the Department of Medicine, Emory University School of Medicine.

9 Davidsohn, Israel. Irregular Isoagglutinins. J. A. M. A. 120: 1288-1292 (Dec. 19) 1942.

CASE 4—A Negro man aged 63 had extremely severe right-sided pleural pain with limitation of respiration, resulting from an infarct of the lower lobe of the right lung. Pain and hyperesthesia extended down over the abdomen as far as the inguinal ligament. Procaine block of the lower six intercostal nerves on the right brought immediate complete and permanent relief of the pain.

CASE 5—A Negro man aged 35, after seven days of complete consolidation of the right lung, developed severe pleuritic pain over the anterior and lateral right thoracic wall. The pain radiated to the umbilicus and over the right upper abdominal quadrant. Intercostal block of the right fourth, fifth, seventh and eighth nerves relieved the pain permanently.

CASE 6—A Negro man aged 20 with atypical pneumonia had intense right-sided pleurisy of eighteen hours' duration. Injection of the seventh and eighth right intercostal nerves gave complete and permanent relief.

CASE 7—A Negro man aged 25 with atypical pneumonia, atelectasis of the lower lobe of the right lung, displacement of the mediastinum, pronounced increase in respiratory rate and a moderate degree of cyanosis had for twenty-four hours complained of severe pleuritic pain occurring laterally and anteriorly over both walls of the chest. Bilateral intercostal block of the ninth, tenth and eleventh nerves produced immediate relief with clearing of the cyanosis and a sharp drop in the respiratory rate. Eighteen hours later the pain recurred on the left but prompt reinjection of the nerves abolished his symptoms permanently.

CASE 8—A Negro woman aged 24 complained bitterly of pleuritic pain associated with pneumonia involving the lower lobe of the right lung. The pain had been intense for thirty-six hours. Infiltration of the seventh, eighth and ninth right intercostal nerves caused immediate cessation of pain, and the patient was able to sleep.

CASE 9—A Negro man aged 27 entered the hospital with severe bilateral pain in the chest, aggravated by coughing on deep inspiration. He had pneumonia of the lower lobe of the right lung and pleurisy on the left, as evidenced by an audible friction rub. Accompanying the process there was a definite increase in respiratory rate. The patient was unable to raise any sputum. The ninth, tenth and eleventh intercostal nerves were blocked bilaterally with complete and permanent relief of pain, a drop in the respiratory rate and definite mental changes, as shown by lack of anxiety and the ability to sleep. After the block the patient was able to cough without pain and a specimen of sputum was easily obtained.

CASE 10—A Negro youth aged 15 was admitted to the hospital with pneumonia of the middle and lower lobes of the right lung. Eight hours prior to admission he had severe pleuritic pain. Immediately on admission to the hospital block of the right eighth and ninth intercostal nerves gave immediate and permanent relief of pain.

CASE 11—A Negro man aged 30 had pneumonia involving the lower lobe of the left lung, accompanied by severe pleuritic pain, hyperesthesia over a wide area, increased respiratory rate and inability to cough. Procaine block of the lower seven intercostal nerves on the left reduced the respiratory rate, abolished the pain and hyperesthesia, and rendered coughing less painful. This made it possible for the patient to obtain rest and sleep, which had not been accomplished since onset of the pneumonia.

CASE 12—A Negro youth aged 17 with pneumonia involving the lower lobe of the right lung and associated pleural pain of severe nature had the right seventh, eighth, ninth and tenth intercostal nerves blocked, with immediate and complete relief of the pleural pain.

CASE 13—A Negro man aged 39 with pneumonia of the middle and lower lobes of the right lung and agonizing pleural pain of fourteen hours' duration had the right sixth intercostal nerve blocked, with relief of pain for about ten minutes. The pain recurred over the lower three nerves, which were again injected. There was complete disappearance of the pain. Twenty

minutes later the pain recurred but was of much less severity than on previous occasions. At this point the patient was given morphine sulfate $\frac{1}{6}$ grain (0.011 Gm.) and in a short time was asleep. There was no recurrence of the pain after the patient awakened.

CASE 14—A Negro woman aged 49 entered the hospital with pneumonia of the middle and lower lobes of the right lung and pleuritic pain of eight hours' duration. Injection of the right seventh, eighth and ninth intercostal nerves produced immediate and permanent relief of the pain.

COMMENT

Thirteen patients who had pneumonia and a fourteenth who had pulmonary infarction were suffering with severe lancinating pleural pain aggravated by cough and deep inspiration. All but 3 of those with pneumonia had audible friction rubs. The respiratory rate was definitely increased. Six patients had pain referred to an upper abdominal quadrant and the periumbilical region. In the patient with pulmonary infarction the pain extended 2 fingerbreadths below the inguinal ligament. The pain of each of these patients was relieved by intercostal nerve block within five to ten minutes after the injection was completed. Pain recurred in only 2 patients. In the first the pain returned eighteen hours after the initial block. Reinjection of the nerves produced permanent and complete relief from the pain. In the second the pain reappeared ten minutes after the first injection. Reinfiltration of the nerves provided complete relief for twenty minutes, but the pain again recurred in about one half of the area supplied by the blocked nerves. The patient was given morphine $\frac{1}{6}$ grain (0.011 Gm.), shortly after which he fell asleep and the pain did not recur on awakening. The majority of the patients had considerable tachypnea, and in these the character of respiration was materially altered following intercostal block. It became deeper, slower and more regular, with obliteration of the respiratory grunt.

The immediate relief of the pain after procaine block was to be expected. However the prolonged disappearance of the pain came as a distinct surprise. At first it was thought to be a mere coincidence, but later it became clear that prolonged relief of pleural pain was the usual result of intercostal nerve block. The anesthetic effect of the procaine lasted only a short time. Therefore, prolonged anesthesia could not account for the permanent disappearance of the pain. The increase in depth of respiration was striking in all cases as soon as the pain was completely abolished, and it may be that the increased motion of the parietal pleura was in some way connected with the permanent relief of pain. Recent studies have demonstrated that prolonged relief of pain from a sprained ankle may result from the combination of local anesthesia and motion.¹ As in the case of pleural pain, the disappearance of pain in the ankle persists long after the anesthetic effect of the procaine has worn off.

Other authors have injected procaine hydrochloride for relief of pleural pain. Weiss and Davis² recommended subcutaneous infiltration of the hyperesthetic skin. Schmur³ advised local infiltration of the pleura. Both of these methods are successful if the area of hyperesthesia is well localized, but they are not practical when the pain is widespread. The method of intercostal block described here has proved infinitely more simple and time saving for me.

SUMMARY

In a series of 14 consecutive cases severe pleural pain was relieved effectively by intercostal nerve block. The resultant improvement in the general condition of the patients was striking. Anxiety disappeared and most patients fell asleep shortly after the procedure was completed. For some this was the first rest in many hours.

UNIVERSAL O BLOOD TRANSFUSION COMBINATION OF POOLED PLASMA AND O CELLS

JOSEPH LEWIS, M.D., NEW YORK
Transfusionist, Beth Israel Hospital, Blood Bank Assistant,
Metropolitan Hospital

The importance of blood grouping first demonstrated by Landsteiner, opened the way for transfusion as a safe therapeutic measure. By cross matching, the occasional reactions due to incompatibility of bloods were avoided.

The use of universal blood donors was first described by Ottenberg¹ in 1911. Since then, especially because of objections raised by Coca,² Hesse,³ and others,⁴ the indiscriminate use of the universal donor has been condemned by many. The presence of agglutinins in a titer higher than 1:16 is considered unsafe. The serum of the universal donor has an increased titer in 3 per cent of donors according to Coca and in a higher percentage according to Hesse (a titer of 1:32 or over in 12 per cent against A cells and 32 per cent against B cells). The desire to curb the indiscriminate use of the universal donor has resulted in a sanitary code regulation in New York State, January 1941, prohibiting the use of universal O donors unless the isoeagglutinins are of low titer by actual titration. Witelsky, Klendshoj and Swanson⁵ suggested that isoeagglutinins anti A and anti B may be neutralized by the addition of their homologous antigens to O blood in order to make it safer for universal donor transfusions. On the other hand many, including Rosenthal and Vogel⁶ in a series of 819 cases, found no higher incidence of reactions than with homologous blood. However, universal donors were used only in urgent cases, and cross matching was usually done.

In order to overcome the reactions from this type transfusion, it has occurred to me that the use of pooled plasma with O cells would constitute a safer universal blood. Since O cells contain no agglutinogens nothing is to be feared from their use, provided proper typing is performed. Again, since the incidence of reactions from pooled plasma has been minimal (about 1 per cent), one may dismiss plasma as a source of unusual reactions. The combination of O cells with pooled plasma should make the ideal universal blood.

Obviously this procedure applies only to institutions with blood banks. On collection, after typing and Kohn testing the bloods are centrifuged. Plasma is pooled from at least eight donors. Either the freshly pooled plasma can be added to the cells of type O (or other types if large pools are obtained), or stored, banked pooled plasma, the titer of which has been determined, may be added to the cells. The pooling diminishes the titer of the isoeagglutinins mainly by dilution and to some extent also through neutralization of the isoeagglutinins by group substances in solution. In either event there is no waste of red cells, since they are conserved with or in pooled plasma. In this way no typing of the recipient or cross matching would be necessary at any time when this combination of O cells and pooled plasma is used.

If the bank has sufficient donations of O cells these may be used with pooled plasma for whole blood transfusions or the cells may be used in saline or dextrose suspensions. Likewise the A, B and AB cells may be used if necessary in their respective blood groups if there is an insufficient supply of

O cells. Additional O cells may be obtained from the Red Cross blood centers. At the expiration of the allotted time—seventy-two hours by some groups or seven to ten days or longer by others—the unused blood will yield pooled plasma for further use.

SUMMARY

The combination of O cells with pooled plasma constitutes an ideal and safer and economical medium of universal blood, because of dilution of agglutinins, than the indiscriminate use of ordinary universal O blood.

PHOSPHATIS IN THE THERAPY OF CHEMICAL BURNS

EDWARD POSER, M.D., AND ERWIN HAAS, PH.D., CHICAGO

The use of a phosphate buffer for the treatment of burns caused by acidic or basic substances is suggested by the following considerations. The customary therapy of chemical burns has definite disadvantages, particularly when such sensitive tissues as the cornea are involved. In order to achieve rapid and penetrating neutralization of acids and bases, high concentrations of the antidote are required. This prerequisite for successful therapy is not fulfilled by the commonly used reagents, since they can be applied only in dilute solutions because of their unphysiologic nature.

As a further requirement for effective treatment it is essential to maintain the hydrogen ion concentration of the antidote at a physiologic level. The following examples illustrate that the aforementioned requirements are not at all satisfied by the therapeutic agents in general use. A 5 per cent solution of acetic acid, recommended in textbooks for the treatment of burns caused by strong alkali, has a pH of about 2, whereas a 5 per cent solution of sodium bicarbonate, used heretofore for neutralizing acid burns, has a pH of 9. As the physiologic pH is approximately 7, it becomes evident that in the first case the hydrogen ion concentration is a hundred thousand times too high while in the second case it is a hundred times too low. Such deviations from biologically compatible limits are bound to result in harmful effects, especially in the treatment of delicate tissues as those of the eye.

In the past, chemical burns due to acids or bases required different antidotes. Therefore a knowledge of the chemistry of the toxic agent and a history supplied by the patient were indispensable. Since the immediate neutralization of the injurious chemical is the most important feature of the treatment, designed to reduce to a minimum penetration of the tissues, valuable time may have been lost in gathering the information mentioned. Future surgical or medical care may never restore what could have been saved by adequate, immediate treatment.

The phosphate buffer recommended here for the neutralization of chemical burns is prepared by dissolving 70 Gm of monobasic potassium phosphate, KH_2PO_4 , and 180 Gm of dibasic sodium phosphate, $Na_2HPO_4 \cdot 12H_2O$ in 850 cc of water. The concentration of the solution thus obtained is molar with respect to phosphate, but as the phosphates are physiologically occurring substances they can be safely employed in such high concentrations. Thereby prompt neutralization of the offending chemical is insured without introducing new complications, at the same time limiting the degree of burn and the corresponding amount of scarring that usually results. The phosphate solution is neutral, $pH = 7$, and, owing to its buffering action, the hydrogen ion concentration will always remain in the physiologic range. The fact that it can be used equally well for the neutralization of either acids or bases is demonstrated by the following examples:

Application of the concentrated phosphate buffer to a normal eye merely results in some hyperemia of the conjunctival tissue, which will disappear on the following day. Using a more dilute solution of the buffer would eliminate even this slight discomfort but would at the same time diminish the effectiveness of the antidote.

SUMMARY

1 Certain unphysiologic antidotes are much too acidic or alkaline for the treatment of vulnerable tissues.

2 Burns caused by acids or bases required a different treatment which necessitated a knowledge of the chemistry of the offending substance.

3 Phosphate buffer has none of these disadvantages. It is neutral in its reaction, can be employed safely in high concentration to assure rapid and penetrating neutralization and is equally well suited for the treatment of injuries caused by acidic or basic chemicals.

Special Article

AMERICAN HEALTH RESORTS

IMPORTANCE OF REST, EXERCISE AND DIETARY REGULATION IN THE SPA REGIMEN

M. B. JARMAN, M.D.
HOT SPRINGS, VA.

These special articles on spa therapy and American health resorts were prepared under the direction of the Committee on American Health Resorts. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the committee. These articles may be published later as a Handbook on Health Resorts.

It is difficult to write a readable article about the obvious. Remove the three items mentioned in the title from a regimen and there remains no regimen either at a spa or at any other institution designed to preserve or promote health. There will be no references in this paper to the historical background of spas. This has been covered in another article. As for the literature, discussions of rest, exercise and diet in treatment occur over and over. When a spa regimen is mentioned these three items stand out. In textbooks on medicine, however, it is difficult to find references to a spa or a spa regimen. I have examined the 1941 edition of an excellent textbook of medicine.¹ One hundred and forty-four leading American physicians contributed to this volume. More space is devoted to discussions of treatment than was the practice in textbooks of medicine a few years ago. Even so, in the sixty pages of finely printed index I was unable to find the word spa or spas, although the words rest, exercise and diet in connection with the types of patients who go to spas occur frequently. Why not call a spa a spa?

WHAT IS A SPA?

A spa is an institution, built around a "mineral" spring or group of such springs, so equipped and staffed as to utilize the waters from these springs in conjunction with other therapeutic agencies for health purposes. The springs determine the location of spas,

but it takes more than a group of springs to make a spa. The "other therapeutic agencies" are of great variety and will be referred to in other articles in this series, but a spa is not a spa without some of them. This article is concerned with three of the more important of these "therapeutic agencies."

WHO GOES TO SPAS?

Rest, exercise and diet will be discussed briefly as applied to the types of patients who patronize spas. For this purpose some attempt has been made to find out who goes to spas.

In general, patrons of spas consist of middle aged and elderly persons who are normal in health and want to remain so, and persons of the same age groups who are suffering from certain of the chronic diseases or convalescing from surgical operations or acute diseases.

A survey² covering the period from 1933 to 1936 inclusive made at an American spa classified the 6,315 patients treated during this period under the following headings on the basis of the patients' chief complaint: heart and circulatory disorders, including variations of blood pressure, 30.8 per cent, "rheumatic" conditions, including arthritis, myositis, fibrositis and neuritis, 23.7 per cent, gastrointestinal ailments, including those of the liver and gallbladder, 17.6 per cent, nervous conditions, including both functional and organic diseases, 8.4 per cent, metabolic diseases, including diabetes, obesity and endocrine disorders, 4.1 per cent, skin diseases (noninfectious), 2.1 per cent, miscellaneous, 3.2 per cent, no disease, including general debility, 10.1 per cent.

At another American spa³ during the period from 1937 to 1941 inclusive the patients were classed as follows on the basis of the chief complaint or the patient's reason for seeking treatment at a spa: normal, 18.3 per cent, obese, 11.1 per cent, "rheumatic," 23.6 per cent, disorders of the nervous system, 10.5 per cent, disorders of the circulatory system, 11 per cent, disorders of the digestive system, 5 per cent, convalescents, 7.8 per cent, fatigue or exhaustion, 6.3 per cent, miscellaneous, 6.4 per cent. Efforts to get similar information from other spas so far have been unavailing, but with these figures in mind, even though the classes listed are not clearly defined, the question "Who goes to American spas?" is partly answered.

REST AND EXERCISE

Rest and exercise as applied to these groups in the spa regimen will be discussed together because, except for certain special exercises such as corrective exercises and certain forms of local rest such as that obtained by splints or collapse therapy, rest and exercise are simply different degrees of the same thing—just like heat and cold. Absolute rest is analogous to absolute zero temperature and just about as difficult to attain.

For those normal persons who make up 10 to 20 per cent of spa patrons the importance of the proper balance of rest and exercise is admitted. In a recently published article by Piersol⁴ this statement appears:

2 McClellan, Walter S. Report of a Survey Made at the Saratoga Spa and Presented in Form of a Chart at the Fifteenth Annual Meeting of the American Congress of Physical Therapy, September 1936.

3 From my own unpublished record. The Homestead Hot Spring, Va.

4 Pierol, George Morris. The Value of Physical Therapy in Internal Medicine. J. A. M. A. 117: 1835 (Nov. 29) 1941.

1 Cecil, Russell L. A Textbook of Medicine by American Authors, edited by Russell I. Cecil, ed. 5 Philadelphia W. B. Saunders Company, 1943.

"It is generally admitted that the proper kind and amount of physical exercise is essential for the maintenance of good health. In this country during the past fifty years the trend in exercise has been toward the less formal gymnastics, more sport activities and a decided increase in the employment of corrective exercise."

At a spa exercise for the normal person is usually chosen from the great variety of "sport activities" available—walking on measured, scenic walking trails, golf, tennis, swimming, horseback riding, badminton or other outdoor sports. The kind and amount of such exercise determined on can be fitted easily into the patient's regimen. The degree of medical supervision of this exercise varies greatly from none at all at some spas to that conforming to a systematic program at others. In the supervision of the patient an important point is to protect an enthusiast in golf, tennis or other sport from becoming intemperate in his otherwise wholesome pastime. The patient's rest, like his exercise, should be regular as to time and sufficient in amount as is the case with normal persons whether at spas or elsewhere. Opportunity for an abundance of rest is the secret back of the success of many resorts and is a feature *par excellence* that all spas should offer. Spas provide the setting and the facilities for carrying out a well balanced program of rest and wholesome exercise away from the scene of the person's usual activities.

Rest and Exercise for Arthritic Patients—Approximately 1 patient in 4 who seeks treatment at spas is a victim of one of several maladies often grouped under the heading "rheumatic disease." Most of these patients suffer from atrophic or hypertrophic arthritis. Some suffer from the articular manifestations of gout. Victims of tuberculous arthritis, acute infectious arthritis and acute rheumatic fever go to spas only by mistake. For purposes of this article the rarer forms of arthritis may be ignored and the discussion limited to atrophic and hypertrophic arthritis.

Physicians may differ as to details in the treatment of these two forms of arthritis, but in the emphasis placed on rest there is general agreement. This applies to local rest of the involved joints and to general physical and mental rest. In the active stage of atrophic arthritis, local rest and the prevention of deformity may be obtained by the use of splints. It is my opinion that a spa is not the best place to treat a patient whose disease is so active as to require a splint, though it can of course be done. It is in the field of general physical and mental rest that spas have much to offer.

Definitely prescribed periods of rest constitute an important part of the regimen of all arthritic patients at spas, and many spas provide a suitable environment for obtaining such rest away from the stress and strain of business, home and family responsibilities.

Exercises make up an important part of the regimen of arthritic patients who go to spas. Passive exercises are often used to maintain mobility of the joints of patients suffering from atrophic arthritis. These are usually preceded by the application of heat and sometimes massage. The heat may be given as a hot bath, or in some instances active and passive exercises are

given while the patient is under water. Limitation of articular motion is not so pronounced in hypertrophic as in atrophic arthritis, and mobility can be maintained more easily. The amount and intensity of exercise suitable for patients suffering from arthritis will depend on the activity of the disease and the general condition of the patient. As a rule any exercise which results in undue fatigue or pain does more harm than good. The better equipped spas have attendants trained to give these exercises intelligently. The mechanical apparatus with which some spas are supplied is of little practical use in providing suitable exercises for arthritic patients.

Rest and Exercise for Obese Patients—An undetermined number of patrons of spas seek treatment solely because they are overweight. In my own practice slightly more than 11 per cent belong to this group. In addition to the patients who seek treatment solely because they are overweight there are many others who are actually overweight but who go to spas for other reasons. Many patients seeking treatment for arthritis, cardiovascular disease, nervous disorders and other troubles are definitely overweight. When all of these are taken into account it is readily seen that control of weight—which usually means reduction of weight—is a most important item in the regimen of a spa. A few patients who are overweight because of endocrine abnormalities do go to spas, but in my opinion their problems can be solved better elsewhere.

With few exceptions the reduction of body weight depends on the restriction of caloric intake and the stimulation of metabolism. Restriction of caloric intake is purely a matter of control of diet. Stimulation of body metabolism may be accomplished by exercises, baths and drugs. Cold baths will stimulate metabolism, and hot baths of sufficient degree and duration to raise body temperature will increase metabolism. It is my opinion that baths of either type are of minor importance in a weight reducing regimen. Diet will be discussed later, and drugs will be disposed of by pointing out that the dangers involved in the use of such drugs as dinitrophenol or the misuse of thyroid have no place in a spa regimen for the type of patients under discussion.

As for exercises as a means of stimulating metabolism, it can be said that spas provide a wide choice of them under conditions which minimize the drudgery of exercise for that not inconsiderable number of people to whom it is a drudgery. In addition to the wholesome "sport activities" mentioned previously, some spas are equipped with mechanical apparatus such as vibratory and percussion devices, rowing machines and stationary bicycles for both the active and the passive exercise of the voluntary muscles. The use of the vibratory and percussion devices may serve as a substitute for manual massage over which it has no demonstrable advantages. It has not been demonstrated that even heavy massage—mechanical or manual—will remove deposits of adipose tissue. Such treatment when applied to the abdomen may even be dangerous. The mechanical apparatus for active exercises does supply the necessary incentive to certain types of patients to take needed exercise which would not be taken otherwise. In my opinion, to this degree only does such apparatus serve a useful purpose in a weight reducing regimen.

Rest and Exercise for Patients Suffering from Cardiovascular Disease—At one American spa slightly more than 30 per cent of the patients suffer from some disorder of the circulatory system. In no large group of patients is the proper regulation of rest and exercise more important. Almost without exception, when the treatment of cardiovascular disease is discussed emphasis is placed on the proper kind and amount of rest needed. The patients suffering from cardiovascular disease who go to spas are usually those who have a chronic disease or who are convalescing from an acute disease. For this reason those spas to which such patients go should be adapted by virtue of their natural resources for patients of this type and staffed by physicians and technicians who are qualified to direct and handle them. It goes without saying that not all spas are so adapted and staffed.

In articles on the subject, such statements as these are found: "The matter of rest periods is one of the first things to be discussed. . . . some patients spend one period of twenty-four hours a week in bed."

It [a spa] endeavors to teach a suitable way of living for the individual and has to do largely with rest, relaxation, exercise, diet and the teaching of a calm philosophical outlook in general and upon the cardiovascular handicap in particular.⁶ Some physicians of spas "point out that the spa treatment rarely if ever consists solely of drinking or bathing in spring water, but that many other factors, such as rest, diet, exercise, diversion and climate, play a definite part."⁷ "The types of physical therapy indicated in cardiovascular disease are rest, voluntary exercise,"⁸ Finally, "Physical therapy in vascular disease is most often beneficial when given in an environment far removed from the patient's usual surroundings."⁸

It is said that "hearts are bettered for taking some part of the amount of exercise which they can tolerate without embarrassment."⁶ Systems of exercises have been worked out to provide for this. The Stokes-Oertel graduated hill climbing exercise is an example. This is often combined with restriction of intake of fluids and reduction of body weight by dietary control. A system of resistant exercises for patients suffering from chronic heart disease was developed by Dr. Theodor Schott and his brother August. This originated at a spa—Bad Nauheim—and is still in good repute with internists who are familiar with it. Spas equipped to treat patients suffering from chronic cardiovascular disease provide other suitable means for exercise. Walking trails accurately measured with reference both to distance and to grade enable the physician to give specific directions to his patients regarding exercise. Sports suited to the requirements of such patients are provided. These may include games requiring little physical exertion, such as croquet, or those requiring more effort, such as golf. Even the golf course may be designed for patients suffering from chronic cardiovascular disease, that is, be comparatively level throughout, as is the case at one American spa whose golf course does not contain any grade exceeding 4 per cent. It has been referred to as a "therapeutic golf course."

⁸ Stroud, W. D. and Comstock, C. R. Principles and Practice of Physical Therapy, edited by Pemberton, Mock and Coulter. Hagerstown, Md. W. F. Prior Company, vol. 1, chapter 13, p. 27.

Enough has been written to indicate the attention given to detail at some spas in providing for the rest and exercise which play so important a role in the regimen of these patients. The effectiveness with which such facilities are utilized depends on the quality of the medical direction just as the effectiveness of any other therapeutic agent depends on the skill, judgment and integrity of the physician who directs its application.

Rest and Exercise for Other Patients—About two thirds of spa patrons are included in the groups already discussed. The remaining third—those who suffer from disorders of the nervous system, disorders of the digestive tract, fatigue or exhaustion and others listed as miscellaneous—will not be discussed in detail. The regimen for such patients will have to be individualized. Since they are all convalescents or suffering from chronic disease, it is obvious that any such regimen would include scheduled, planned rest and exercise. Spas are well suited to provide such a regimen in an environment conducive to the patient's feeling of well being. Between 5 and 10 per cent of patrons of spas go to them merely because they are tired. Many others listed under other headings who go to spas are tired but are not aware of it. These patients usually suffer from nervous and mental fatigue. The mere act of getting away from home or business affords such patients rest of the kind needed. With the restful atmosphere which should prevail and with the wide range of types of exercises from which to choose a suitable regimen with reference to rest, exercise and diet can be adjusted to the needs of these patients if competent medical direction is provided. Failure is more likely to result from lack of medical direction than from other factors involved.

DIET

I am convinced that the therapeutic measure most frequently advised by physicians is rest. I am convinced also that a thought uppermost in the minds of patients who go to spas—and one about which there is much confusion—centers around matters pertaining to diet. There are reasons why diet should be a matter of concern. Not the least of these is the fact that most people are confronted with it three or more times daily year in and year out. There are reasons for confusion in the lay mind about such matters. It is not necessary to itemize the reasons, but that confusion is widespread. I am sure no physician will doubt. When a patient at a spa says "I have been on a very strict diet," a little questioning as to what he—or more often she—means by a strict diet will usually elicit one of the following replies: "I don't eat white bread," "I don't eat potatoes," "I don't eat red meat" or "I don't eat desserts." I should say that with the exception of carefully instructed patients suffering from diabetes, those suffering from peptic ulcer who have been well handled and those treated for allergy, this is not an exaggerated picture of the lay conception of what is meant by a "strict diet."

Detailed discussion of the diet for each type of patient who goes to spas cannot be given here. I believe it will not be denied that control of diet is an important item in the regimen of such patients. Physicians at spas have access to the same sources of information in dietetics both in health and in disease as do physicians generally. Control of diet is a matter of applying available knowledge to patients who happen to be at spas.

For the 10 to 20 per cent of normal persons who go to spas the diet should be that for normal persons under similar conditions of activity elsewhere. The discussion of the diet for a normal man or woman does not belong here.

For the 25 per cent of patients of spas who suffer from arthritis the diet should be that adapted to the individual needs of the same type of arthritic patient whether he is at a spa or elsewhere. Books, sections of books⁹ and numerous articles have been written on just what such a diet should be. The prescribing physician has to exercise the same discretion that he is called on to exercise in many other situations. Dr. Walter Bauer made in analysis of the various types of diets proposed for arthritic patients. Familiarity with the contents of his article¹⁰ will prove helpful in keeping the prescribing physician properly oriented.

For the undetermined but large number of people at spas who are overweight control of diet is by far the most important consideration. The principles governing control of diet at spas do not differ in any essential way from similar methods elsewhere. A regimen which includes suitable control of diet along with regulated exercise will prove effective in the reduction of surplus weight. Such a regimen can be carried out at spas without the use of drugs, excessive sweating, purging or other forms of dehydration. The success and safety of the regimen will depend on the adequacy of the medical supervision. "Mineral waters, except for possible laxative effects, have no peculiar virtue"¹¹ in a reducing regimen.

For that other large group of patients of spas—patients suffering from cardiovascular diseases—the diet, for the most part is directed toward the control of weight. In some cases the intake of fluids and mineral salts has to be taken into account. A spa organized for the care of such patients usually provides physicians capable of guiding them in such matters.

For the remaining third of patients who go to spas the diet should be adjusted to the individual needs of each patient. In the well organized spas this usually can be done. Except for the rest he might get, there is no reason for a patient who has a duodenal ulcer to go to a spa, but, should he go, there is no reason why he should not be able to carry out his dietary program. The same applies to patients who have diabetes, disease of the gallbladder, "colitis" or an irritable colon, and so for the others. It all boils down to the same thing. It is this. The principle governing dietary measures are the same for a given type of human being whether he happens to be living at a spa, in a hospital or at home. Since a large number of patients suffering from a great variety of chronic diseases do go to spas—whether they should or should not is beside the point—it means that if spas are to maintain a standard at which they can command the confidence of the medical profession they must provide medical supervision and control of such quality as to guide these patients properly in health matters whether they pertain to rest, exercise, diet or any other "therapeutic agent."

Dietary fads should not have any place in the regimen of a spa.

Council on Medical Service and Public Relations

THE COUNCIL HAS AUTHORIZED THE PUBLICATION OF THE FOLLOWING
STATEMENT
J. W. HOLLOWAY JR., Acting Secretary

A STATEMENT OF GENERAL POLICIES

Pursuant to carrying out the duties imposed on it by the House of Delegates, the Council has adopted the following general policies:

1 The Council on Medical Service and Public Relations recognizes the desirability of widespread distribution of the benefits of medical science, it encourages evolution in the methods of administering medical care, subject to the basic principles necessary to the maintenance of scientific standards and the quality of the service rendered.

It is not in the public interest that the removal of economic barriers to medical service should be utilized as a subterfuge to overturn the whole order of medical practice. Removal of economic barriers should be an object in itself.

It is in the public interest that the standards of medical education be constantly raised, that medical research be constantly increased and that graduate and postgraduate medical education be energetically developed. Curative medicine, preventive medicine, public health medicine, research medicine and medical education all are indispensable factors in promoting the health, comfort and happiness of the nation.

2 The Council through its executive committee and secretary shall analyze proposed legislation affecting medical service. Its officers are instructed to provide advice to the various state medical organizations as well as to legislative committees concerning the effects of the proposed legislation. It shall likewise be the duty of its officers to offer constructive suggestions to bureaus and legislative committees on the subject of medical service.

3 The Council approves the principle of voluntary hospital insurance programs but disapproves the inclusion of medical services in those contracts for the reasons adopted by the House of Delegates at the 1943 meeting.

4 The Council approves voluntary prepayment medical service under the control of state and county medical societies in accordance with the principles adopted by the House of Delegates in 1938. The medical profession has always been strongly opposed to compulsory health insurance because (1) it does not reach the unemployed class, (2) it results in a bureaucratic control of medicine and interposes a third party between the physician and the patient, (3) it results in mass medicine which is neither art nor science, (4) it is inordinately expensive and (5) regulations, red tape and interference render good medical care impossible. Propaganda to the contrary notwithstanding, organized medicine in general, and the American Medical Association in particular, have never opposed group medicine prepayment or group medical practice as such. The American Medical Association and the medical profession as a whole have opposed any scheme which on the face of it renders good medical care impossible. That group medicine has not been opposed as such is evidenced by the fact that there are many groups operating in the United States which have the approval of the medical profession, and members of these groups are and have been officials in the national and state medical organizations. That group medicine is the Utopia for the whole population, however, is not probable. It may be and possibly is the answer for certain communities and certain industrial groups if the medical groups are so organized and operated as to deliver good medical care.

5 The Council believes that many emergency measures now in force should cease following the end of hostilities.

6 The Council believes that the medical profession should attempt to establish the most cordial relationships possible with allied professions.

7 There is no official affiliation between the American Medical Association and the National Physicians Committee.

⁹ Pemberton, Ralph. Arthritis and Rheumatoid Conditions, Philadelphia, Lea & Febiger, 1929.

¹⁰ Bauer, Walter. What Should a Patient with Arthritis Eat? J. A. M. A. 104:1 (Jan 5) 1935.

¹¹ McEster, James C. Nutrition and Diet in Health and Disease, ed. 3, Philadelphia, W. B. Saunders Company, 1939, p. 443.

However, since it is the purpose of the National Physicians Committee to enlighten the public concerning contributions which American medicine has made and is making in behalf of the individual and the nation as a whole, it is the opinion of the Council that the medical profession may well support the activities of the National Physicians Committee and other organizations of like aims.

8 American medicine and this Council owe a responsibility to our colleagues who are making personal sacrifices to answer the call of the armed forces. Therefore the Council expresses the desire to cooperate with the medical committee on postwar planning in order to assist our colleagues in reestablishing themselves in the practice of medicine and in the preservation of the American system of medicine.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN L. SMITH, M.D., Secretary

ASCORBIC ACID (See New and Nonofficial Remedies, 1943, p. 600)

The following dosage forms have been accepted

AMERICAN PHARMACEUTICAL CO., INC., NEW YORK

Ascorbic Acid (*Crystals*) 1 ounce and 5 ounce packages

Tablets Ascorbic Acid 25 mg, 50 mg and 100 mg

NICOTINIC ACID (See New and Nonofficial Remedies, 1943, p. 596)

The following dosage forms have been accepted

AMERICAN PHARMACEUTICAL CO., INC., NEW YORK

Nicotinic Acid (*Powder*) 1 ounce, ¼ pound and 1 pound packages

Tablets Nicotinic Acid 25 mg and 100 mg

PENTOBARBITAL SODIUM (See New and Nonofficial Remedies, 1943, p. 495)

The following dosage form has been accepted

THE WARREN-TEED PRODUCTS CO., COLUMBUS, OHIO

Capsules Pentobarbital Sodium 0.1 Gm

SULFATHIAZOLE (See New and Nonofficial Remedies, 1943, p. 182)

The following dosage form has been accepted

GEORGE A. BREON AND COMPANY, KANSAS CITY, MO

Sterators Sterile Sulfathiazole (*Crystals*) 5 Gm

SULFANILAMIDE (See New and Nonofficial Remedies, 1943, p. 175)

The following dosage form has been accepted

GEORGE A. BREON AND COMPANY, KANSAS CITY, MO

Sterators Sterile Sulfanilamide (*Crystals*) 5 Gm

DIGITALIS (See New and Nonofficial Remedies, 1943, p. 289)

The following additional dosage form has been accepted

JOHN WIETH & BROTHER, INC., PHILADELPHIA

Capsules Digitalis Leaf Defatted ½ U S P Unit

MAGNESIUM TRISILICATE (See New and Nonofficial Remedies, 1943, p. 369)

The following dosage form has been accepted

BUNNROUGHS WELLCOME & CO., INC., NEW YORK

Tablets Magnesium Trisilicate 0.486 Gm

EPHEDRINE SULFATE (See New and Nonofficial Remedies, 1943, p. 256)

The following dosage form has been accepted

BUNNROUGHS WELLCOME & CO., INC., NEW YORK

Solution Ephedrine Sulfate 3 per Cent Preserved with chlorobutanol 0.5 per cent, 1 fluidounce and 1 pint bottles

Council on Foods and Nutrition

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
JAMES S. McPHERSON, Chairman

SCOPE OF COUNCIL

The passage of the Federal Food, Drug and Cosmetic Act, June 25, 1938, greatly strengthened the power of the federal government to deal with the labeling of foods, drugs and cosmetics, the maintenance of standards of quality and related problems. Many of the activities of the American Medical Association's Council on Foods and Nutrition have dealt with such questions. These activities were initiated and carried on by the Council at the home office of the American Medical Association as a public service. The well known seal plan of the Council was devised as a means of encouraging firms to secure as much scientific information as possible concerning their products, to label these products honestly and informatively, and to advertise them in ways that avoid all misleading implications. The success with which all of this has been done is readily evident to any one who will undertake an examination of the Council's book *Accepted Foods*, published in 1939, in which are listed 1,653 firms whose 2,706 individual products carried the seal at that time. The Council wishes to record its appreciation of the willingness of these firms to cooperate in the wording of their labels and their advertising and in the maintenance of high standards of quality in recognition of which the Seal of Acceptance was given.

For some time the Council has had under advisement the question of limitation of its scope of activities. Various reasons have operated to cause this, but the most cogent one has been the passage of the Food, Drug and Cosmetic Act, and the continued advance which the Food and Drug Administration has been able to make under this act in establishing standards of identity for various foods and rules regarding the labeling of them. At its annual meeting held July 23 in Chicago the Council finally took action to limit the number of specific products eligible for the seal. It was voted to restrict the use of the seal to "special purpose" foods, which may be defined as "any food promoted for a special group of the population in relation to health, growth and development." Familiar examples of special purpose foods would be those prepared especially for babies, and products designed for feeding invalids. Products that may be valuable, but which are offered for use by the population in general, are classified as "general purpose" foods, and under the action voted by the Council are, with perhaps a few exceptions outside its scope and therefore will no longer be considered for the seal. It is evident that by its action the Council has signified that so far as the use of the seal on individual products is concerned, it intends to devote its attention particularly to foods that stand in very definite relation to specific medical and health problems. The current popular interest in the science of nutrition, stimulated in considerable part by the war, the nutrition program of agencies of the government the Red Cross and other organizations can no doubt be relied on to develop interest in the greater use of more valuable foods by the population at large. The Council also voted, however, to consider what might at first sight appear to be exceptions to this category of special purpose foods if such action seems desirable and in the public interest. The wording of this part of the motion is as follows: Except that the Council may, under special circumstances consider the acceptance of any product when its nutritional importance or the claims made for it seem significant for the public health. Thus the Council has signified its continued freedom of action to deal with any food product if such action is deemed especially important.

Firms whose general purpose foods now carry the seal are allowed the period of one year from date of publication of this notice during which to dispose of their supply of remaining labels now carrying the seal.

SATURDAY NOVEMBER 6, 1943

EPIDEMIC HEPATITIS, OR CATARRHAL
JAUNDICE

Until recently there has not been essential modification of the original concept of catarrhal jaundice advanced by Bamberger in 1855 and supported by Virchow in 1865. Now, however, numerous clinically similar cases have appeared in epidemic proportions in troops and in civilian groups in almost all countries. Study of these events has resulted in a reconsideration of the basic interpretations. Formerly the initial lesion in this disease was considered a gastroduodenitis followed by spread of "catarrh" to the epithelium of the bile ducts which thereby produced obstructive jaundice. The occurrence of a biphasic van den Bergh reaction stimulated doubts of this simple explanation and suggested that damage of the liver must be present either alone or in combination with biliary obstruction. This altered theory has given rise to a changed nomenclature in which the term epidemic hepatitis or infective hepatitis (the former probably being preferable) has tended to replace the older term of catarrhal jaundice.

Cameron¹ reports studies at two army general hospitals in Palestine during 1940 and 1941, when "infective hepatitis" was epidemic among the troops. The clinical picture of the disease developed in collaboration with Colville is based on the clinical records of 170 cases. The minimum incubation period is apparently thirty-two days, but in many cases much longer. The initial stages of the disease resemble sand fly fever, although in epidemic hepatitis the headache is less intense and the characteristic pain behind and on movement of the eyes found in sand fly fever is here lacking. Initial severe anorexia is a striking and almost diagnostic feature. Disinclination for smoking is common, nausea is frequent but vomiting unusual. Abdominal discomfort, with a tendency to constipation rather than diarrhea, occurs frequently. Fever was present in all cases observed during the preicteric stage, usually it is of a regular type varying between 99 and 103 F

and continuing for three to six days, when jaundice appears. With the development of jaundice the initial symptoms rapidly subside. The depth of jaundice varies from a light coloration of the conjunctiva to a deep icterus involving the whole body. It lasts an average of twenty-one days, reaches a maximum intensity at five days and has a range varying from five to seventy-two days. Bradycardia occurs as soon as the development of jaundice but this is not diagnostic since it seems to accompany almost all virus infections. Transient enlargement of the liver was noted in 97 of the 170 cases. There was a scattering of other signs or symptoms, the most frequent being splenic enlargement, which was encountered in 46 cases. Five points are of major importance for diagnosis in the preicteric stage: anorexia, abdominal discomfort with or without hepatic enlargement and tenderness, absence of leukocytosis, increased urobilinogen in the urine, and histamine wheal test for latent jaundice. Deaths did not occur in the entire series, most patients recovered in thirty-five days. Treatment should include isolation of the patient and a minimum of one month hospitalization. The presence of clay colored feces was considered an indication for a low fat and cholesterol diet, in cases in which the feces remained persistently pale, bile salts were given so that fat could be introduced into the diet. All patients must refrain from alcohol for a minimum period of three months on the theory that alcohol lowers the resistance of the liver.

The infection is believed to be due to a virus. A number of animal inoculation experiments have been made and several attempts to transmit the disease by insect vectors. Van Rooyen and Gordon² obtained bile and stomach washings from 10 patients and fed large volumes of each specimen to animals. The animals employed were mice, white rats, jerboas, rabbits, guinea pigs, monkeys, Abyssinian baboons, a young pig and 3 kittens. In addition blood containing 1 per cent sodium citrate which had been withdrawn in 20 proved cases was introduced into each of these animals by various routes—subcutaneously, intravenously, intraperitoneally, intracerebrally, intratesticularly and intracorneally. Definite results were not obtained. Similar experiments were also performed by Cameron. Samples of blood were withdrawn from patients as soon as possible after diagnosis. Part of the blood was allowed to clot, but sodium citrate was added to the larger portion. Monkeys, guinea pigs, dogs, mice, rats and hamsters were employed as the experimental animals. Some of the animals received whole blood or plasma without further treatment. For others a leukocytic fraction was prepared by centrifugation of the citrated blood for an hour, the resulting sediment being then suspended in saline solution and injected. Careful clinical observations, blood counts

² Van Rooyen C E and Gordon Ian J Royal Army M Corps
 79 19 (Nov) 1942

and temperature charts were made. In the guinea pigs alone some suggestive observations were recorded, including leukopenia appearing five to twenty days after injection in all of them. One animal showed necrosis of liver cells and round cell infiltration of the portal tract. Because of the simultaneous occurrence of jaundice in horses it has been necessary to exclude piroplasmiasis as a cause of human hepatitis. Cameron reports experiments carried out by Captains Colville and Hynds in which 6 horses were injected with blood or serum from 6 patients with hepatitis. Repeated blood counts and close veterinary observation failed to reveal any effects.

It is agreed by Cameron, by Van Rooyen and Gordon and by others that jaundice may or may not be present in this disease. Van Rooyen and Gordon did not observe indications of obstruction or catarrh of the bile passages and therefore believe that the jaundice is toxic and due primarily to damage of the liver parenchymal cell. All are agreed that this disease is highly contagious and emphasize the necessity for treating it as a serious liver disease and one in which lowered general resistance such as that which occurs so commonly in military campaigns is a predisposing factor. Much further work is needed in order to determine the responsible agent, the mode of spread and possible relations to certain animal diseases.

THE IRRITANT EFFECT OF CATGUT

The irritant effect of catgut on living tissues has been commented on in a previous editorial¹ in *THE JOURNAL*. The clinical experience of Halstead, Jenkins, Kraissl, Whipple and others and the experimental demonstration by Meleney stress this undesirable effect of surgical gut as compared with some of the non-absorbable suture materials. These observers believed that the irritating effect was due to the catgut per se. Halstead believed that buried catgut serves as culture medium for saprophytic organisms which are carried into it from the deep epithelium and the follicles of the skin. Kraissl demonstrated the possibility of an allergic reaction to catgut in a patient with edema of the edges and disruption of the abdominal wall. The irritant effect manifests itself in the wound by induration, redness, serum formation, lowered tissue resistance with increased susceptibility to infection from organisms introduced at operation or from the blood stream, and retardation of healing.

The recent experiments by Dunham and Jenkins,² however, establish that it is the tubing fluid in which the catgut is kept that is responsible for the irritating effect. Surgical catgut has customarily been provided

in glass tubes with either an anhydrous hydrocarbon liquid for boilable catgut or an alcoholic solution for nonboilable gut. The anhydrous boilable tubing fluids have generally been xylene. These investigators state that the alcoholic solutions of numerous products examined by them contain appreciable quantities of hydrocarbon, which they believe is a residuum from the heat sterilization process, not removed during the process of manufacture before the alcoholic solution was added and the tube sealed. They believe this to be a common factor for the catgut, regardless of whether it was boilable or nonboilable. Their experiments clearly demonstrate that a fairly substantial part of the tissue irritation characteristic of catgut is due to the irritant hydrocarbon carried into the tissues with the gut. The presence of alcohol in the gut from non-boilable tubing fluid or from dipping boilable gut in 70 per cent alcohol to induce pliability contributes in part to the tissue irritation. However, they believe that the action of the alcohol is of secondary importance. They also found that those products which were characterized by excessive exudate and profuse polymorphonuclear leukocytic invasion of surrounding tissues generally had a high hydrocarbon content of the tubing fluid. They further suggest that the polymorphonuclear leukocytic response, which in their previous experiments was shown to hasten the onset of the mechanism of absorption, is probably induced by the extraneous tubing fluid irritants rather than by the catgut per se. Once this leukocytic mechanism of absorption has started to break down the catgut, it is not unlikely that the products of breakdown may further act as irritants to the tissues, so that the irritation inaugurated by the tubing fluid may be enhanced or prolonged. The combination of these two factors may be important in the tissue reaction to catgut.

Analytic study by Sidwell³ of the American Medical Association Chemical Laboratory demonstrated the presence of up to 14 per cent of the water insoluble liquid aromatic hydrocarbons present in some of the samples of the nonboilable surgical gut tubing fluids examined. The physical and chemical properties of the water insoluble materials isolated from various specimens led to the conclusion that the tubing fluid contains material closely related to a coal tar distillate known as "xylene fraction" or solvent naphtha. Jenkins and Dunham⁴ conclude that, from the point of view of obtaining optimum wound healing in surgery, the introduction of tubing fluid irritants into the tissue with suture material is not in the best interests of the patient or the surgeon. The elimination of tubing fluid irritants from surgical gut should result in better clinical results with the use of absorbable suture material.

MULTIPLICATION OF BACTERIOPHAGE IN ANIMAL TISSUES

Bacteriophage lysis is inhibited by blood serum, leukocytes bile and tissue debris. Many bacteriologists have concluded, therefore, that bacteriophage would necessarily be an ineffective therapeutic agent in most regions of the animal body. This conclusion apparently is premature as shown by recent demonstrations of the multiplication of bacteriophage in chick embryos¹ and in infected brain tissues of white mice.² In both cases the proliferation is associated with positive therapeutic effects.

The chorionallantoic membrane of the developing chick embryo is a useful medium for the cultivation of many viruses and bacteria. Weil and Volentine,³ for example, showed that *Bacterium shigae* will proliferate on this membrane and will usually cause death of the embryo in from two to four days; increase in the bacterial count is demonstrable as early as five hours after the bacillus is placed on the membrane. At this five hour period the Rakieten¹ introduced 0.1 cc of the corresponding anti-Shiga phage on the infected membrane. This reduced the usual mortality rate from 100 per cent to 25 per cent. Examination of egg material collected from the survivors showed a uniformly increased titer of bacteriophage. The conclusion must be that antidyentery bacteriophage does multiply (or is multiplied) in living tissues and does result in local sterilization of the tissues.

Somewhat more detailed studies of the same phenomenon have just been reported by Dubos² of Harvard University, who made use of the experimental disease resulting from intracerebral inoculation of dysentery bacillus in white mice. This disease takes the form of a meningitis, which is usually fatal in from three to ten days. Extensive multiplication of the Shiga bacillus takes place in the infected brain without a generalized septicemia.

In preliminary tests Dubos found that anti-Shiga bacteriophage introduced intraperitoneally into normal mice can be detected in the brain within one hour after injection. The concentration of bacteriophage per gram of brain, however, is invariably much less than the concentration in the blood stream. In mice infected intracerebrally with the Shiga bacillus there is in contrast an apparent rapid and massive elective localization of the bacteriophage in the infected brain tissues, the concentration being much higher than in the blood stream. The high titer in the brain cannot be accounted for solely as a result of elective localization of circulating bacteriophage but implies a local multiplication of particles of bacteriophage.

Dubos also found that intraperitoneal injection of a sufficiently large dose of active bacteriophage reduces the mortality rate from 96.4 per cent to 28 per cent in Shiga infected white mice. The control mice were treated with the same doses of heat inactivated bacteriophage or with bacteriophage free Shiga autolysate. The minimum dose of bacteriophage necessary to produce these therapeutic effects was not determined. It was shown, however, that one million particles of bacteriophage (plaque count) injected intraperitoneally were without demonstrable therapeutic effects. Dubos's routine therapeutic dose was ten billion bacteriophage particles injected intraperitoneally. This was contained in about 1 cc of phage lysed Shiga filtrate. This mouse dose would be roughly equivalent to 3 liters of bacteriophage filtrate for a 150 pound (68 Kg) man. Whether or not the bacteriophage would be more effective if injected directly into the brain tissues has not yet been determined.

THE GENERAL MEDICAL COUNCIL OF GREAT BRITAIN AND "INFAMOUS CONDUCT IN A PROFESSIONAL RESPECT"

In a lecture delivered to the staff and students of Guy's Hospital Medical and Dental School, Sir Herbert Lightfoot Eason,¹ president of the General Medical Council, pointed out that the lay press in Great Britain has not thus far learned to differentiate between the British Medical Association and the General Medical Council. This incidentally is a difference not clear to many American physicians. The British Medical Association is a body established by the medical profession whereas the General Medical Council was appointed primarily for the benefit of the public.

The short preamble to the Medical Act of 1858 sums up the function of the Medical Council: "Whereas it is expedient that persons requiring medical aid should be enabled to distinguish qualified from unqualified medical practitioners." The council distinguishes between the qualified and the unqualified practitioner, although it does not debar the unqualified practitioner from the practice of medicine and surgery.

The General Medical Council performs two functions. In exercising its educational function it inspects all the qualifying examinations of the licensing bodies and issues recommendations as to amendments to the curriculum. It does not impose any restriction on the intellectual freedom of the registered medical practitioner. He may hold any view in medicine or surgery that he prefers, there are, however, certain restrictions as to his conduct. These restrictions are included in section 29 of the act and constitute the second important function of the council. Information as to misconduct

¹ Eason, H. L. "Infamous Conduct in a Professional Respect: What a Practitioner May and May Not Do," *Guy's Hosp. Gaz.* 57: 147 (July 10) 1943.

on the part of any doctor is forwarded to the council from every magistrate's court, every court of justice and every police office in the kingdom. While the council records every offense or conviction against medical practitioners, its principal interest is in that which relates to "infamous conduct in a professional respect." Such conduct has been defined by Lord Justice Lopes as follows:

If a medical man in the pursuit of his profession has done something with regard to it which will be reasonably regarded as disgraceful or dishonourable by his professional brethren of good repute and competency, then it is open to the General Medical Council if that be shown to say that he has been guilty of infamous conduct in a professional respect.

The question is not merely whether what a medical man has done would be an infamous thing for any one else but a medical man to do. He might do an infamous thing which would be infamous in any one else, but if it is not done in a professional respect it does not come within section 29.

The particular section lists the following offenses which are considered as "infamous conduct in a professional respect": signing certificates which do not meet with the particular requirements, assisting unqualified practitioners in treatment of patients and drunkenness. The last named offense appears to be the most common "crime" and is particularly serious if a practitioner is found to be drunk while driving a car.

Of special interest are three offenses which are grouped as the "three A's": Advertising, Abortion and Adultery. Advertising is not permitted, the prohibition includes such types of advertising as newspaper interviews with a doctor, who may be referred to as "a distinguished surgeon" or "a well known physician." As to abortion, it is emphasized that, whatever views one holds regarding it, under the laws of Great Britain abortion is a felony which is punishable by terms of penal servitude. The General Medical Council takes the attitude that the council is no judge of morals and that its function is not to punish the members of the medical profession but rather to protect the public. Adultery per se would not be considered "infamous conduct in a professional respect," and the General Medical Council takes no note of adultery as such. If, however, it is adultery with a person who is a patient, the wife of a patient or the member of a patient's family, then the council may say that the doctor has abused his position of trust. The sincerity of this statement is evident from the advice Sir Eason offers which is "If you must have irregular relationships with women, you should keep those relationships away from the professional side of your life."

Like most English institutions, the General Medical Council has considerable legal authority but derives most of its power from its moral authority. It has succeeded in molding the British medical profession into an organic whole without at the same time interfering with the healthy rivalry and individualism of

the various educational institutions. The council controls the standards of medical education by its power to represent to the Privy Council that a licensing authority should have its license revoked because its teaching and its examinations are not sufficient, and the council would take the same step if any licensing body should attempt to impose any particular theory of medicine or surgery. The council may require information to discover these points and may appoint inspectors and visitors to the various authorities.

The General Medical Council also provides for the publication of the British Pharmacopeia, a function entrusted in our country to the United States Pharmacopeal Convention.

Current Comment

THE NEED FOR PHYSICAL AND OCCUPATIONAL THERAPY TECHNICIANS IN WARTIME PHYSICAL RECONSTRUCTION

Large numbers of physical therapy and occupational therapy technicians are needed to meet the expanding requirements of wartime physical reconstruction. The Army already has physical therapy technicians serving in a hundred and forty Army hospitals within the continental limits of the United States and in thirty-four Army hospitals overseas. Recently the announcement was made that the Army still needs a thousand more physical therapy technicians. The Navy, the Veterans Administration, the Public Health Service and the civilian hospitals also require large numbers of physical and occupational therapy technicians to assist in rehabilitation of persons disabled by the war. The distinguished educator Ernest J. Jaqua, president of Scripps College in California, now serving as director of the Professional and Technical Division of the Bureau of Training, War Manpower Commission, recently made a tour among middle and far western universities in the interest of physical and occupational therapy. He concluded that it would be necessary to develop additional training schools at larger educational centers. The views expressed by this educator are gratifying to physicians interested in physical rehabilitation. Some of his observations follow:

Hearty cooperation between the liberal arts and medical faculties is essential for complete success of a program of training in these fields. Whenever possible the two courses of study should be under joint administration since the first year of technical training can be practically identical. There is much overlapping in actual operation.

The general supervision of the training program can best be entrusted to the medical school since all courses of study must be approved by the Council on Medical Education and Hospitals of the American Medical Association, or to a joint committee of the medical and arts faculties the former providing the chairman. It is important to recognize the dominant medical implications from the outset.

The chief difficulty in establishing strong new schools of physical and occupational therapy at this time is the scarcity of qualified teachers. In the case of physical therapy this means doctors who have specialized in this field in medical

chool and have been directors of physical therapy departments in hospitals. These men are few and many of the best ones are now in the Army. As for occupational therapy teachers, they too are scarce and military hospitals are endeavoring to rapidly establish new departments.

The founding of several new schools of physical and occupational therapy in state universities under experienced joint leadership where both medical and arts courses and hospital facilities are immediately available will have the double effect of giving added professional standing to the rapidly developing medical fields and at the same time discouraging the establishment of departments in institutions lacking medical affiliations.

Perhaps the deepest impression gained from this survey of physical and occupational therapy schools is one of admiration for the splendid pioneer work of the older schools in the face of half-hearted appreciation and support by the medical profession generally and only the vaguest knowledge of their importance on the part of the lay public. The first approved schools have steadily raised their professional standing, extended the range and quality of their courses of study (especially in medical subjects) and proved beyond all doubt the indispensable nature of their services to the medical profession. Indeed, thoughtful observers are deeply convinced, and the war will drive home this point with increasing poignancy, that the medical school or hospital which does not now take active measures to provide these services will some day be awakened to the fact that certain features of the magnificent procession of health have moved past while they were unaware of their presence or unmindful of their significance.

IS TUBERCULOSIS DISAPPEARING?

The mortality rate from tuberculosis 'was cut in half during the first twenty years and then halved again by 1940, that is, the 1940 rate was less than one-fourth that at the beginning of the century'.¹ The average for the three years 1939-1941 established an all time low record of 45.9 per hundred thousand of population. While this decline has been general for all ages and races, the rate of decline in the productive years 20 to 45 has been slower than in later years. "The remarkable decrease in tuberculosis mortality, which resulted in lowering tuberculosis from one of first rank in numerical importance to seventh, conceals the fact that this favorable situation does not hold for all age groups, from early adulthood to age 35 it is still the first killer." The percentage of tuberculosis deaths to deaths from other causes by age starts at a low point in the younger ages, increases rapidly to reach a maximum at the most productive age periods, then declines continuously thereafter. Mortality for tuberculosis is highest in cities of 100,000 or more population. For males it declines steadily in cities of 2,500 to 100,000. It is lowest in rural areas. The deaths of females are lowest in cities of 2,500 to 100,000 population, although the difference is not great. The rate for males is considerably higher than for females throughout the population. Tuberculosis is still much more fatal among the nonwhite races, but the rate of decline is more rapid in the colored population. "Many factors have contributed to the extraordinary achievements in the control of tuberculosis as reflected in the reduction of the death rate from around 200 per hundred thousand at the beginning of the cen-

tury to less than 45 per hundred thousand at present. These factors are in the main the results of man's endeavor to control his environment. Some are tangible, such as the discovery of the causative organism and modes of transmission of the disease, many others are not so definite and may be stated vaguely to be the results of improvements in the 'standard of living'. The direct relationship of any one factor to the reduction of tuberculosis mortality may be difficult to prove. The combination of all factors, however, has reduced the mortality rate in the course of half a century to such an extent that the eradication of tuberculosis is within the realm of possibility."

LIEUT. GEN. MARK W. CLARK EULOGIZES MEDICAL CORPS' SERVICES

Under Medicine and the War, in this issue of THE JOURNAL, appears a copy of a letter sent by Lieut. Gen. Mark W. Clark, commanding General of the Fifth Army, to Major Gen. Norman T. Kirk, Surgeon General of the United States Army, eulogizing the magnificent service rendered by the medical department in the invasion of Salerno Bay. The efficiency of the performance is testimony to the wholehearted, sacrificing effort of the medical profession of the United States. In June 1940 Gen. George Dunham, delegate from the United States Army Medical Corps to the House of Delegates of the American Medical Association, presented a call to the medical profession to mobilize for the war. Under Surg. Gen. James C. Magee thousands of physicians and Medical Corps men were enrolled and units like the evacuation hospitals, to which special praise is tendered, were established. Under Major Gen. Norman T. Kirk the medical profession continues to respond with courage and self-sacrifice. The letter of General Clark is special testimony to the magnificent work of the battalion surgeons who move up with the troops to the front lines and render their aid under enemy fire. General Clark emphasizes particularly the closeness of the medical service to the actual front. As the war intensifies and as our Army drives on to ultimate victory the demand on the medical profession is likely to become greater, the need for its service more imminent. At this time several thousand more doctors are needed and must be enrolled. The letter of General Clark should be an inspiration to every man who can possibly meet the call to come forward and offer his services.

MEMORIAL TO WILLIAM BEAUMONT

A permanent memorial to William Beaumont, known as the founder of our modern knowledge of the physiology of the stomach, has been assured by the transfer of the historical "Early House" on Mackinac Island to public ownership. In this house Alexis St. Martin, the French Canadian voyageur who was the subject of Beaumont's famous studies, received his accidental shotgun wound on June 6, 1822. In the actual work of restoration technical advice will be obtained from a committee of the Michigan State Medical Society, the National Park Survey and other agencies and historical sources.

¹ Yerushalmy, J., Hilleboe, H. E., and Palmer, C. E. Tuberculosis Mortality in the United States 1939-1941, Pub. Health Rep. 58:1457 (Oct. 1) 1943.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeons General of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

GENERAL CLARK EULOGIZES MEDICAL SERVICES AT SALERNO

HEADQUARTERS FIFTH ARMY

Office of the Commanding General

A P O No 464, U S Army

Major General Norman T Kirk
Surgeon General, U S Army
War Department
Washington, D C

In the field
25 September 1943

Dear General Kirk

I desire to express the highest commendation for the wonderfully fine work performed by the medical units of this Army. Their devotion to duty under the hazardous and trying circumstances of the landing in Salerno Bay and their skill and efficient administration reflect the best traditions of the Service. Many wounded officers and men, who will eventually be restored to full health, would have died but for the effective work of the Medical Corps. I am especially well pleased with the performance of the Surgeon Fifth Army. He has done a magnificent job.

From the first landing to the date of this letter, 3,335 casualties have been admitted to Fifth Army hospitals. The first hospital opened within 3 to 5 miles of the front lines. The next hospital began to function the following day still closer and under the most difficult conditions. Neither hospital had any nurses when opened. Thus far there have been only 42 deaths in the hospitals. Thirty-two of these cases were those of U S personnel who died from wounds. Five were U S personnel who died from disease or injuries, 5 were enemy who died of wounds. Many of those who survived would never have reached a hospital alive had the hospitals been located at a normal distance from the front.

Two thousand and sixty-one cases have been evacuated to North Africa by air and sea.

The beach medical service was superior. One medical battalion distinguished itself on the beaches under heavy fire early in the operation. I shall recommend that the unit be cited for its gallant work under terrible conditions.

The medical supply system began to function according to plan with the assault wave, and despite the most difficult conditions it rapidly developed to the highest state of efficiency.

Among the difficulties with which the medical services have had to cope were the loss of the entire equipment of our third evacuation hospital and the bombing of a hospital ship which was bringing the nurses. Fortunately only one nurse was injured, and all are again on their way to Italy to rejoin their units.

The whole performance of the Fifth Army medical services has been most heartening to me and has been of incalculable aid in the operation. I have been so favorably impressed with their performance that I cannot forbear to write you this personal letter to tell you of my gratitude and admiration.

Mark W Clark,
Lieutenant General, U S Army,
Commanding

ARMY

THE BRUNS GENERAL HOSPITAL

The Bruns General Hospital which was formally dedicated on September 22 is located in Santa Fe, N. M. The hospital was activated on February 18 and the formal flu season was celebrated April 19 at which time the first patient was admitted. Although the hospital was built with a thousand bed capacity recent construction will soon afford 1500 beds. It is of cantonment type composed of open and closed wards, officers' and nurses' quarters, barracks, utility shops, warehouses, and a chapel. All the wards, quarters and barracks are connected by either closed or covered walks.

The Bruns General Hospital was named in honor of the late Col. Earl Harvey Bruns who was recognized as one of the world's leading authorities on pulmonary tuberculosis. The hospital has not been designated as one for any particular specialty but rather a typical general hospital. It is equipped to care for surgical, medical, eye, ear, nose and throat, genito-urinary and neurologic and psychiatric cases.

The medical officers assigned to the Bruns General Hospital as of September 27 were as follows:

1. Col. Larry B. McVee, commander, general
1. Lt. Col. Robert J. Wilcox, executive officer, public relations officer
1. Capt. Charles B. Alfeld, M. C., reception and evacuation officer
1. Capt. City, Mo.

MEDICAL SERVICE

1. Major D. K. K. M. C., chief, Livermore, Ill.
1. Major Marshall W. Martin, M. C., assistant chief, Burlington, Wis.
1. Capt. O. J. K. M. C., Ill. P. O. Texas
1. Capt. J. O. H. M. C., Chicago
1. Capt. H. E. T. M. C., chief of orthopedic section, Detroit
1. Capt. J. W. H. D. M. C., Dubois, Pa.
1. 1st Lieut. Paul I. Martin, M. C., Omaha
1. 1st Lieut. Herman H. Levin, M. C., Newville, Pa.
1. 1st Lieut. Joseph F. Kauer, M. C., Bronx, N. Y.
1. 1st Lieut. John A. Underwood, Jr., M. C., Parkville, Mo.
1. 1st Lieut. Robert K. Vandemark, M. C., Stoughton, Wis.

MEDICAL SERVICE

Major George J. Kastlin, M. C., chief, Pittsburgh
Major Samuel I. Koopferstein, M. C., assistant chief, Jersey City, N. J.
Major John D. Ferrara, M. C., Jacksonville, Fla.
Major Jacob A. Fande, M. C., Sioux City, Iowa
Capt. Harry L. Fischer, M. C., Detroit
Capt. Erich P. Hausner, M. C., Amsterdam, N. Y.
Capt. Herbert B. Ellis, Milton, N. M.
Capt. Max J. Yacht, M. C., Brooklyn
1st Lieut. Edward J. Brazinski, M. C., Perth Amboy, N. J.
1st Lieut. Clifford H. Kall, M. C., Grafton, Wis.
1st Lieut. Juan L. Larralde, M. C., New York
1st Lieut. Ralph G. Lightly, M. C., Sussville, Pa.
1st Lieut. Theodore J. Talbot, M. C., New Brighton, N. Y.
1st Lieut. John C. Patterson, M. C., Freehold, N. J.
1st Lieut. Hyman L. Bass, M. C., Bronx, N. Y.

NEUROPSYCHIATRIC SERVICE

1st Lieut. Col. Cullen W. Irish, M. C., chief, Los Angeles
Major Jacob N. Friedman, M. C., New York
Capt. Robert E. McDade, M. C., Philadelphia
1st Lieut. Morris V. Borenstein, M. C., Springfield, Mass.
1st Lieut. Edward G. Feldman, M. C., Chicago

EYE, EAR, NOSE AND THROAT

Major Gordon H. Pumphrey, M. C., chief, Mount Vernon, Ohio
Capt. Earl W. Martens, M. C., Milwaukee
1st Lieut. Edward Schwartz, M. C., Chester, Pa.

GENITOURINARY SERVICE

Capt. Frank L. Larkin, M. C., Scranton, Pa.

LABORATORY SERVICE

Major Elson B. Helwig, M. C., chief, St. Louis
1st Lieut. Ralph C. Brown, M. C., Winnetka, Ill.
1st Lieut. Daniel E. Johnson, Sn. C., Muncie, Ill.
2d Lieut. Charles C. Croft, Sn. C., Washington, D. C.

ROENTGENOLOGIC SERVICE

Major Murray M. Friedman, M. C., Altoona, Pa.

OUTPATIENT SERVICE

Capt. Herbert S. Weichsel, M. C., Poughkeepsie, N. Y.

DENTAL SERVICE

Major Oscar J. Ogren, D. C., chief, Minneapolis
Capt. Eldon L. Armer, D. C., Tucson, Ariz.
Capt. Eldon L. Njos, D. C., Baldwin, Wis.
1st Lieut. Richard L. Mosgrove, D. C., Lincoln, Neb.
1st Lieut. Frank A. Lemone, D. C., Shreveport, La.
1st Lieut. Arthur O. McGowan, D. C., Kansas City, Kan.
1st Lieut. Gustave P. Brickbauer, D. C., Milwaukee

COL STANHOPE BAYNE-JONES APPOINTED
DIRECTOR OF TYPHUS COMMISSION

The War Department, Washington, D. C., announced on October 21 the appointment of Col. Stanhope Bayne-Jones, M. C., A. U. S., as director of the United States of America Typhus Commission. Colonel Bayne-Jones succeeds Brig. Gen. Leon A. Fox, U. S. Army, who asked to be relieved as director and appointed field director in order to give all his time to the field work of the commission, which has been operating abroad, particularly in the Middle East, since the first of this year. Colonel Bayne-Jones takes over the directorship in addition to his other duties as assistant director, Preventive Medicine Division, Office of the Surgeon General, where the main office of the commission has been established. In addition to General Fox and Colonel Bayne-Jones, members of the commission include Major Gen. LeRoy Lutes, U. S. Army, Rear Admiral Charles S. Stephenson (MC), U. S. Navy, Brig. Gen. James Stevens Simmons, M. C., U. S. Army, Dr. R. E. Dyer, director of the National Institute of Health, U. S. Public Health Service, Col. Harry Plotz, M. C., A. U. S., Col. William I. Wilson, M. C., U. S. Army, Comdr. Thomas J. Carter (MC), U. S. Navy, Dr. Norman H. Topping, U. S. Public Health Service, Major John C. Snyder, M. C., A. U. S., Major Charles M. Wheeler, Sanitary Corps, A. U. S., Lieut. Comdr. W. B. McAllister (MC), USNR, Lieut. Comdr. A. Yeomans, USNR, Dr. Alexander G. Gilliam, U. S. Public Health Service, and Capt. Byron L. Bennett, Sanitary Corps, A. U. S.

Colonel Bayne-Jones is a former dean of Yale University School of Medicine, New Haven, Conn., and was professor of bacteriology at that university when ordered to active duty early in 1942. He graduated from Johns Hopkins University School of Medicine, Baltimore, in 1914, entered the medical reserve corps in 1915 and served throughout the World War. From May 1917 to March 1918 he was attached to the British Expeditionary Force in France and Italy and later with the American Expeditionary Forces in France and Germany. He has been decorated with the British Military Cross, the French Croix de Guerre and the Silver Star with two Oak Leaf Clusters.

SPECIAL HOSPITAL ESTABLISHED
TO TREAT BURNS

According to a recent report from Algiers, Lieut. Col. Edward A. Krause, formerly of Washington, D. C., has been named head of the special hospital established to treat burns received on the battle field, under the Army's new "selective hospitalization plan." Col. Edward D. Churchill, former professor of surgery at Harvard University, Boston, and now on duty in Algiers, said that the new system whereby soldiers with special types of injuries are sent to special hospitals, such as that headed by Lieutenant Colonel Krause, had three large advantages. Naturally the establishment of centers specifying the treatment of various types of casualties will render better service to the men wounded in battle. Second, these centers also will be educational centers where surgeons and specialists from other hospitals may observe techniques. Then too, technical data to check on the results of surgical management and point the way to improved methods can be assembled.

U. S. ARMY UTILIZING TALENTS OF
CHICAGO NEGRO DOCTORS

Many prominent Negro physicians from Chicago are looking after the health and battle care of Negro troops in United States camps and overseas. Fort Huachuca, which is located on the side of a mountain between Bisbee and Nogales, Ariz., and which is said to be the principal Negro training center in the country in the sense of providing finishing work with combat troops, is the home of some 20,000 Negro soldiers. There the 92d Division recently celebrated its first anniversary as an activated division. Lieut. Col. Median O. Bousfield, former member of the Chicago Board of Education, is in command of the station hospital at Fort Huachuca, Major Harold W. T.

Litcher and Major Roscoe C. Giles, both of Chicago are chief of the medical service and chief of the surgical division respectively. Many of the Negro nurses at Fort Hinchey are from Chicago, as are many of the girls in the WAC battalion there. Major John B. West, former superintendent of Provident Hospital, Chicago, with thirty nurses commands a station hospital in North Africa. En route overseas is another Negro station hospital staff under the command of Major Hugh Simmons of Washington, D. C. with which group Capt. Arthur Thomas, former resident surgeon at Provident Hospital, Chicago is also attached. Another Chicagoan, Major Harvey J. Whitfield, directs the medical detachment with the 365th Engineers at Camp Campbell, Ky.

FOURTH FERRYING GROUP BASE HOSPITAL

A new 150 bed military hospital, the Fourth Ferrying Group base hospital at the Municipal Airport, Memphis, Tenn., was activated without the usual ceremony on February 16 and since has been quietly administering to the medical needs of the air forces ferrying group and other military personnel. The hospital is fully equipped to handle any case from a minor injury to a major surgical operation. Malaria and other tropical diseases contracted by men of the Fourth Ferrying Group during their operations in other parts of the world as well as communicable diseases are also treated there. A modern air conditioned laboratory, a full array of the newest dental and dental surgical equipment, an up to date pharmaceutical department and a medical supply warehouse are at the hospital. Both wards and individual rooms are available for patients. All pilots and crew members of this ferrying group on their return from foreign trips are examined at the hospital before going on rest leave. The entire army personnel of the Fourth Ferrying Group base is given specified immunization shots at specified intervals at the hospital. All pilots are given physical check-ups at regular intervals, and aviation cadets selected by the local Aviation Cadet Examining Board are given their army physical examination at the hospital.

The convalescent program, for men able to be up and about, is one of the outstanding features of the hospital. Each day they are given the opportunity of hearing speakers who are well versed in the various fields pertaining to the air forces, such as pilots who have returned from foreign trips. There are speakers from the outside who keep the men posted on world affairs. The Red Cross Gray Ladies arrange recreational programs, and there are movies and hiking for those men who are able. A day room for patients and enlisted personnel of the hospital is now in the process of construction, which will be equipped for recreational facilities and will also be used for religious services.

Major Lowell C. Smith is commanding officer of the hospital. Other medical officers include:

Capt. Alfred V. Mahoney, executive officer
Capt. Samuel Pritzker, chief of medicine
Capt. David W. Wallwork, chief of surgery
Lieut. Gerald Smith, attending surgeon
Capt. Francis M. Dougherty, flight surgeon
Capt. Eugene H. Bekampes, assistant flight surgeon
Capt. Henry Bernstein, assistant flight surgeon
Lieut. Meyer Leonard Kimmel, assistant flight surgeon
Lieut. Mark L. Beauchamp, chief eye, ear, nose and throat section
Capt. Maurice B. Furlong, ward officer and patients convalescent program
Capt. Jacob David Weinberg, base industrial surgeon and ward surgeon
Lieut. Irvin L. Libecap, assistant chief of surgery
Capt. Samuel M. Klaristenfeld, base medical inspector

LIEUT. COL. W. R. LOVELACE AWARDED DISTINGUISHED FLYING CROSS

Lieut. Col. W. R. Lovelace, chief of the aeromedical unit at Dayton Field, Ohio, has been awarded the Distinguished Flying Cross for heroism beyond the call of duty in recognition of his record altitude jump to test oxygen equipment during the parachute descent. The cross was presented in Washington, D. C., October 20, by Gen. H. H. Arnold, commander of the United States Air Forces.

SEMINOLE COMMISSIONED U. S. ARMY HOSPITAL SHIP

The War Department announced on October 22 the commissioning of the United States Army hospital ship *Seminole*. The vessel has been painted white with a green band and red crosses and it travels alone, fully lighted. It has no armor or armament. The vessel, a former combination freight and passenger ship, is 402 feet long and has a gross tonnage of 5,896 and a net tonnage of 3,514. It was converted by the Transportation Corps of the Army Service Forces. It contains 284 beds for bed type patients and 182 beds for patients able to move about their quarters. The ship is staffed by fifteen medical officers, thirty nurses and eighty-one medical attendants. In addition it has a navy crew. The commanding medical officer is ship commander, but navigation is under command of a naval officer. There are two other hospital ships in operation by the Army, the *Acadia* and the *Shamrock*. Hungarian, Bulgarian, Rumanian, German and Japanese governments have been notified that the *Seminole* is a hospital ship entitled to immunity and protection under the terms of the Hague Convention X, 1907.

LIEUT. COL. PRESTON WHITE AND LIEUT. COL. PAUL SANGER CITED

Citations were presented by the Forty and Eight Voiture to Lieut. Col. Preston White and Lieut. Col. Paul Sanger, both formerly of Charlotte, N. C., as organizers of the 38th Evacuation Hospital Unit, who are overseas serving in North Africa. The formal presentation was made to the wives of Lieutenant Colonel White and Lieutenant Colonel Sanger by Dr. Addison G. Brenizer of Charlotte, who organized a local hospital unit in World War I and who has also been cited by the Forty and Eight Voiture for his recent efforts in organizing Base Hospital No. 111 and securing thirty-five nurses for Base Hospital No. 106.

OFFICERS GRADUATE AT MEDICAL FIELD SERVICE SCHOOL

Graduation exercises were held at the Medical Field Service School, Carlisle Barracks, Pennsylvania, for 344 more officers of the medical department who are now qualified for field duty with troops. The training course taught them the military knowledge necessary for them to be efficient medical department officers, capable of carrying out medical preventive measures and caring for the sick and injured under war conditions. Brig. Gen. Addison D. Davis, commandant of the school, presented the diplomas to the officers.

CAPT. PAUL D. HAHN AWARDED PURPLE HEART

Capt. Paul D. Hahn, Warsaw, Ohio, has been awarded the Purple Heart medal. He received shrapnel wounds in Sicily, according to an item published in the *Uhrichsville (Ohio) Chronicle* of September 24. Captain Hahn was wounded on July 11 in the Gala salient while he was giving first aid to two wounded U. S. soldiers in an evacuation area. The officer and the two men were cut off from their lines for six hours before they were rescued, following a counterattack by a German tank unit.

PRISONERS OF WAR

It has recently been reported that Capt. Alvin C. Powelent, formerly of Newport, Ky., is a prisoner of the Japanese in the Philippines. Captain Powelent graduated from the University of Louisville School of Medicine in 1936 and entered the service March 26, 1941.

First Lieut. Thomas Edward Corcoran, formerly of Rock Rapids, Iowa, was taken prisoner of war in Tunisia Feb. 17, 1943 according to a recent report. Lieutenant Corcoran graduated from the University of Iowa College of Medicine, Iowa City, in 1938 and entered the service Feb. 12, 1941.

MISCELLANEOUS

TRANSPORTATION DIFFICULTIES HAMPER
REMOVAL OF GERMAN WOUNDED

Oberfeldarzt Dr. Wolff in the *Berliner Borsen Zeitung* of August 28 in writing on the work of the army medical service said that for the wounded it is a long road from the moment they are wounded at the front to their arrival at a military hospital in the homeland. The wide spaces of the east, the shortage of railway lines and good transport roads, all the circumstances of a sparsely populated and little civilized country make themselves felt here in the most irritating manner. The removal of the wounded has become one of the hardest problems of this war. Munitions, provisions and material for the armies of millions are pouring to the front on an enormous scale. The outcome of heavy, decisive battles depends on the timely arrival of the supply trains. The few available railway lines are taxed beyond their capacity. Hospital trains. In order to let them through, the necessary supply trains so a part for the front would have to be held up somewhere or other. The transport of wounded by aircraft? The number of those who could pilot the planes is limited on the whole and above all the technical and tactical preconditions for the employment of aircraft and for the landing and starting of the planes would have to be fulfilled. Motor ambulances? Their carrying capacity is even more limited and they too are used in the first place at the front itself to transport the wounded to the main dressing centers and the field hospitals. It is not possible to release ambulances for long journeys on the worst possible roads. In these circumstances quite exceptional situations arise for our medical officers, difficulties of organization which are added to their medical and military duties. The obstacles so it often appears, are insurmountable. But they must be mastered and they are mastered too, often by emergency solutions by means of improvised hospital trains which are established in goods vans (only part of the ordinary passenger carriages are suitable for accommodating stretcher

cases) and which cannot offer the wounded all the comfort and conveniences they deserve. But there is nothing for it, and the wounded are front soldiers, accustomed to discomfort and inconveniences. The chief object is achieved, however the wounded are transported back home.

NERVOUS DISORDERS WIDESPREAD
IN GERMANY

The *Leipziger Neueste Nachrichten* of August 23 states that nowadays the homeland is greatly in need of the nerve specialist. It is a question not so much of serious organic diseases of the nervous system but of the host of so-called nervous disorders which, although they do not endanger life, may have the most serious effect on the well-being, happiness, working capacity and performance of men. In wartime all are subject to heavy burdens. More work has to be done on less food. The hours of sleep are cut and the night's rest is disturbed. Frequently housing conditions are unfavorable and long distances have to be covered in overcrowded means of transport. Families are torn apart. Added to all this are the excitement, worries, mourning and uncertainty about the fate of one's dear ones. Even strong characters are not always equal to such a burden and weaker ones lose their power of resistance and break down. Not every one is capable of withstanding the terror air attacks. No one who does not live in a raided district can have any idea of how horrible an experience it is or of how much firmness and courage are needed to get through a heavy attack. The detonation of the bombs and mines, the collapse of houses, the cries of the wounded and trapped, the fires and the constant danger to life to which every one is exposed in helpless expectation strain one's nerves to the utmost. It is easy to understand that the wounded and trapped who save nothing but their bare lives, whose nearest and dearest are missing and who see themselves surrounded by death and mutilation, fire and devastation suffer a nervous collapse.

ORGANIZATION SECTION

1944 ANNUAL SESSION TO BE HELD IN CHICAGO

Because of information received that it will not be possible for St. Louis to provide adequate hotel accommodations, the annual session of the American Medical Association in 1944, which had been scheduled to be held in St. Louis, has been changed by the Board of Trustees so that it will now be held in Chicago, June 12 to 16.

The meetings of the House of Delegates will be held at the Palmer House and the Scientific Exhibit will be installed in

that hotel. The Technical Exposition will be housed at the Stevens Hotel.

The Council on Scientific Assembly will meet at the offices of the Association in Chicago on December 1 and the Annual Conference of Section Secretaries with the Council will be held on that day for the purpose of making preliminary arrangements for the scientific program to be presented at the next annual session.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status—S. 400 has been reported to and passed by the House, proposing to reorganize the United States Public Health Service. It retains the provision under which for the duration of the present war and for six months thereafter graduates of reputable colleges of osteopathy shall be eligible for appointment "as reserve officers in the Public Health Service." S. 763 has passed the Senate and House, proposing to amend the Selective Training and Service Act of 1940. Among other things, this bill directs the President to appoint a commission of five qualified physicians, one of whom only shall be an Army officer and one only a Naval officer, and the three remaining members qualified physicians not in the employ of the federal government to examine the physical qualification requirements for admission to the Army, Navy and Marine Corps and recommend to the President any changes therein

which it believes can be made without impairing the efficiency of the armed services. H. Res. 328 was reported unfavorably by the House Committee on Military Affairs, proposing to request the President to furnish the House of Representatives certain information with respect to the availability of hospital facilities in the United States. The House after receiving the report of the committee tabled the resolution.

Bills Introduced—H. R. 3530, introduced by Representative King, California, proposes to authorize the construction and extension of certain marine hospitals in Alabama, California, Florida, Illinois, Louisiana, Maine, Maryland, Massachusetts, Michigan, New Mexico, New York, Ohio, Pennsylvania, Texas, Virginia and Washington. H. R. 3542, introduced, by request by Representative Rankin, Mississippi, proposes to provide for the rehabilitation of certain disabled veterans who served between Sept. 16, 1940 and Dec. 7, 1941.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Physicians Needed—The Los Angeles County Civil Service Commission announces examinations for the position of head anesthetist in the Los Angeles County Hospital and for the position of head pathologist at the Olive View Sanatorium, Olive View. Applicants for both positions must have graduated with an M.D. degree from an approved medical school and must have completed a one year internship in an approved hospital. In addition to these requirements, applicants for the head anesthetist position must have at least two years' recent experience in the specialty of anesthesia in a hospital of not less than 200 beds. There is no age requirement. The examination for this "duration of war" position paying from \$345 to \$411 a month will be held in Los Angeles and such other localities as justified by the applications filed. Applicants for the \$345-\$411 a month position of head pathologist must be under 55 years of age and, in addition to the educational requirements, must have at least two years' recent experience as a specialist in clinical pathology, some of which must have been in a responsible administrative and executive capacity. Full information and applications for either of these positions may be obtained from the office of the commission, Room 102 Hall of Records, Los Angeles 12. Applications must be filed on or before November 17.

Annual Symposium on the Heart—The thirteenth annual symposium of the Los Angeles Heart Association will be held in Los Angeles, November 11-12. Dr. Tinsley R. Harrison, professor of medicine, Bowman Gray School of Medicine, Wake Forest College, Winston-Salem, N. C., will be the guest speaker, discussing "The Abuse of Rest in the Treatment of Cardiovascular Disease" and "The Differential Diagnosis of Palpitation." Dr. Harrison will conduct a clinical-pathologic conference and a cardiac clinic. Included among the speakers will be

Dr. William Gordon Garnett Los Angeles, The Practical Management of Patients with Hypertension
Dr. Samuel J. McClelland San Diego The Diagnosis of Rheumatic Fever in Children
Dr. Wilbur A. Beckett Los Angeles On the Importance of Speaking One Heart Language
Dr. Francis M. Smith La Jolla The Importance of Salt and Fluids in the Treatment of Congestive Heart Failure
Major Maurice Elaser Jr. M. R. C. Cardiovascular Disease in an Army General Hospital
Dr. Leon G. Campbell Pasadena The Treatment of Cerebral Vascular Accidents
Dr. Donald E. Griggs Los Angeles The Critical Diagnosis of Angina Pectoris
Dr. Edward C. Rosenow Jr. Pasadena The Importance of the Electrocardiogram in Coronary Artery Disease
Dr. Wilbur Bailey Los Angeles The Place of the Radiologist in the Diagnosis and Treatment of Heart Disease
Dr. William J. Kerr San Francisco One Thousand Draft Rejections for Cardiovascular Conditions
Dr. Howard F. West Los Angeles Nutritional Considerations in Heart Disease
Dr. C. Russell Anderson Los Angeles The Treatment of Cardiovascular Syphilis
Dr. Kendrick A. Smith Los Angeles The Patient with Diabetes and Heart Disease
Dr. John Philip Sampson Santa Monica The Need for Conservatism in the Treatment of Acute Coronary Occlusion

Course at California to Meet Latin American Needs—The University of California will begin on March 1, 1944 a special course in health education to meet the particular requirements of students from the other American countries. Students will be urged, however, to commence their studies not later than December 10 to give time for those who require training in English to secure the necessary instruction. The course in English will be planned to deal with the vocabulary which will be used in the later course in health education and will also serve as an orientation course. The health education course will be given in the School of Public Health now being established and will include training in the principles of public health and hygiene, principles of education and methods, materials and techniques in health education particularly as they apply to conditions in the other republics. Arrangements are being made to appoint one or more experienced public health administrators from the other republics to serve temporarily on the faculty. The class for 1944 will be limited to thirty students. All applicants must give evidence of their intention to undertake service

in public health or in school health work in Latin America after completion of the course. Classroom instruction will be given on the campus at Berkeley, after which there will be supervised field training. Candidates need not be physicians, but persons with prior training or experience in public health work, school health education and related fields will be given preference. Students who are selected for this training by the Institute of Inter-American Affairs will receive monthly stipends adequate to meet their living costs and will be furnished with tuition and transportation from their residence to the University of California and return. All applications will be made through chiefs of party of the Office of the Coordinator of Inter-American Affairs in each republic in accordance with regulations governing the institute training program. Following is a list of the chiefs of party, who should be addressed in care of the American embassy in the respective republics:

Dr. George C. Bergman La Paz Bolivia
Major Linor H. Christopherson, M. C., A. U. S., Rio de Janeiro, Brazil
Dr. Howard B. Shookhoff Bogota Colombia
Dr. David Glusker San Jose Costa Rica
Dr. Theodore I. Gandy, Santiago Chile
Dr. Thomas B. Phinzy Ciudad Trujillo Dominican Republic
Lieut. Wyman R. Stone Quito Ecuador
Lieut. Col. H. R. Van Hovenberg, San Salvador El Salvador
Dr. Robert L. Vought Guatemala City Guatemala
Mr. Ralph S. Howard Jr., Port au Prince Haiti
Dr. Isaac Frank Tullis Jr., Tegucigalpa Honduras
Dr. E. Harold Hinman Mexico D. F. Mexico
Dr. Leonard S. Rosenfeld Managua Nicaragua
Mr. Howard D. Schmidt, Panama City Panama
Dr. Richard J. Plunkett Asuncion Paraguay
Dr. Edward A. Westphal Lima Peru
Lieut. Col. Ernest W. Steel Caracas Venezuela

In other countries, information regarding the course may be secured from the Pan American Sanitary Bureau.

DISTRICT OF COLUMBIA

Personal—Dr. Ludwig G. Lederer, acting chief of the medical department of the Pennsylvania-Central Airlines, has been appointed director of the department. Mr. John A. Linder, Perth Amboy, N. J., has been appointed superintendent of Doctors Hospital, succeeding Mr. O. K. Fike, who resigned to become director of the Miami Valley Hospital at Dayton, Ohio.

Special Meeting on Ophthalmology—On December 4 the department of ophthalmology at George Washington University School of Medicine will hold its semiannual meeting, to which all members of the armed forces are invited. The following case demonstrations will be conducted by members of the staff of the department of ophthalmology:

Drs. William T. Davis and Ernest A. W. Sheppard Anomalies of the Disks
Dr. Edgar Leonard Goodman Pemphigus Conjunctivae
Dr. Ronald A. Cox Bilateral Amblyopia Following Crushed Chest.
Dr. Frank D. Costenbader Retinal Detachment in Childhood
Dr. Richard W. Wilkinson Foreign Body in Cataractous Lens Located by Vogt X-Ray Technique
Dr. Sterling Hockoven Melanoma of the Choroid
Dr. Carmon R. Naples Hypertensive Retinopathy

Col. Frederic H. Thorne, M. C., U. S. Army, will discuss "Military Aspects of Ophthalmology" and Dr. Davis, professor of ophthalmology at the medical school, will give an illustrated address on "Differential Diagnosis of the Vertical Motor Anomalies."

IDAHO

State Medical Election—Dr. Willard O. Clark, Lewiston, was chosen president-elect of the Idaho State Medical Association and Dr. Parley Nelson, Rexburg, was installed as president. Dr. Franklin B. Jeppesen, Boise, is secretary of the group.

ILLINOIS

Campaign Against Bang's Disease—A campaign to eradicate Bang's disease has been begun in Lake County. The Lake County board of supervisors voted funds for the project and state and federal authorities are cooperating in the program, in which every cow will be tested and all dairy calves between 4 and 8 months old vaccinated. Farmers will receive compensation for any reacting cows disposed of through market channels.

Program to Develop Adequate Health Protection in Schools—Health and education officials of the state announced the launching of a program for the development of more adequate health protection in schools throughout Illinois to include a detailed scientific study of school health problems, with the consultant services of Clair E. Turner, Dr. P. H. professor of biology and public health, Massachusetts Institute of Technology, Cambridge, Mass. Preliminary meetings were held in Springfield on October 26 and in Chicago on October 29 to consider the program.

Chicago

University News—Dr. Jacob Meyer, associate professor of medicine, has been promoted to professor of medicine at the University of Illinois College of Medicine effective September 1. Dr. Meyer graduated at Rush Medical College in 1916.

The Belfield Memorial Lecture—Dr. George I. Cahill, professor of urology, Columbia University College of Physicians and Surgeons, New York, delivered the fifteenth annual William I. Belfield Memorial Lecture before the Chicago Urological Society on October 28. His subject was "Hormonal Tumors of the Adrenals."

New Members of Medical Center Commission—New members appointed by Governor Green to serve on the medical center commission include George A. Burr, Joliet, David H. Brill, Albert D. Farwell and Dr. Raymond B. Allen, all of Chicago. The commission is working on the development of a medical center on Chicago's west side. The new members of the commission will take office in December.

INDIANA

Kellogg Grant for Medical Technologists—The W. K. Kellogg Foundation Battle Creek, Mich., has granted \$4,000 to Butler University, Indianapolis, to be used for loans and scholarships in training medical technologists. Following the two to four year preclinical training program at Butler, clinical work is done either at the medical center at Indiana University School of Medicine or at the Methodist Hospital, Indianapolis.

KENTUCKY

State Medical Election—Dr. Oscar O. Miller, Louisville, was named president-elect of the Kentucky State Medical Association at its annual meeting in Louisville on October 6 and Dr. Van A. Stulley, Benton, was installed as president. New vice presidents include Drs. J. Watts Stovall, Grayson James H. Pritchett, Louisville, and William Howe Fuller, Mayfield. Dr. Philip F. Blackerby, Louisville, state health commissioner, was elected secretary of the association and Dr. Amphis W. Davis, Madisonville, was reelected treasurer. During the meeting the house of delegates chose Dr. Thomas Atchison Frazer, Marion, as the "outstanding general practitioner of Kentucky."

MARYLAND

Personal—Dr. Guy B. Anderson, Ellicott City, has resigned as health officer of Howard County. After some special study at the Mayo Clinic, Rochester, Minn., Dr. Anderson plans to return to private practice.

Roscoe R. Hyde Dies—Roscoe Raymond Hyde, Ph.D., professor of immunology and director of laboratories of filtrable viruses since 1932 at Johns Hopkins University School of Hygiene and Public Health, died at Baltimore on September 15. Dr. Hyde graduated at the Indiana State Teachers College, Terre Haute, in 1908, receiving his A.M. and A.B. degrees in 1909 and his Ph.D. degree at Columbia University in 1913. He was assistant in embryology at Indiana University, Bloomington, in 1908-1909, assistant professor and later professor and head of the department of zoology and physiology at Indiana Teachers College serving as lecturer in pathology at the Terre Haute Veterinary College from 1912 to 1919. Joining Johns Hopkins as a fellow in 1918 he subsequently served as associate, associate professor of immunology from 1928 to 1932, and as associate professor of filtrable viruses and head of the department. He was editor of the *American Journal of Hygiene* from 1927 to 1932. Dr. Hyde had been a member of numerous scientific organizations and had written extensively in his field.

MICHIGAN

Inter-American Conference of Schools of Public Health—The Pan American Sanitary Bureau, in cooperation with the Association of Schools of Public Health of the United States and Canada and the W. K. Kellogg Foundation, has called a conference of representatives of the schools of public health in the South, Central and North American countries. The conference will be held in the new School of Public Health of the University of Michigan, Ann Arbor, for four days beginning November 8. In attendance will be representatives from the schools of public health at Harvard, Boston, Yale, New Haven, Conn., Johns Hopkins, Baltimore, Columbia, New York, University of North Carolina, Chapel Hill, University of Toronto, Vanderbilt University, Nashville, Tenn., University of Minnesota, Minneapolis, and University of Michigan, together with representatives from the Rockefeller Foundation,

the W. K. Kellogg Foundation, the Commonwealth Fund, and Office of the Coordinator of Inter-American Affairs, the Department of State, the Pan American Sanitary Bureau and the U. S. Public Health Service. Thomas Parran, surgeon general of the U. S. Public Health Service, will discuss "The Service of the Public Health Schools to the Nation's Health" and Charles-Edward A. Winslow, Dr. P.H., New Haven, Conn., "The Fruits of Inter-American Relations in the Field of Public Health." At one session the education of public health personnel in Mexico, Central and South American countries will be discussed by

Dr. Alberto Zwanck, professor of hygiene, University of Buenos Aires Medical School, Argentina.

Dr. G. H. Paula Souza, director, School of Hygiene, University of São Paulo, Brazil.

Dr. Herman Romero, professor of hygiene, University of Chile Faculty of Medicine, Santiago.

Dr. Mario Prado Ilesort, acting director of the Bacteriologic Institute, Santiago.

Dr. Ortelio Martinez Fortin, professor of hygiene, Havana Medical School, Cuba.

Dr. Manuel Bustamante, professor of hygiene, Mexico D. F.

Dr. Carlos Enrique Paz Soldán, professor of hygiene, Medical School, University of Lima Faculty of Medicine, San Marcos, Peru.

Dr. Federico J. Salveraglio, assistant professor of hygiene at the University of Montevideo Faculty of Medicine, Uruguay.

On Wednesday and Thursday the meetings will be limited to a working committee to consist of one representative from each of the schools of public health and one from each of the interested cooperating agencies. The conference will limit its discussions to the needs of students who aspire to a professional career in the field of public health.

MINNESOTA

Medical Panel for Workmen's Compensation Cases—Governor Elve recently appointed fifteen physicians to serve on a medical panel provided by the last legislature to help decide medical questions arising in workmen's compensation cases. The physicians are Drs. John R. Aurelius, Carl B. Drake and Francis W. Lynch, St. Paul, Harold R. Tregilgas, South St. Paul, Robert G. Allison, Jay A. Myers and Viktor O. Wilson, Minneapolis, Frank J. Elias and John R. McNutt, Duluth, Willis S. Lemon and Charles G. Sutherland, Rochester, Albert J. Wentworth, Mankato, Warren E. Wilson, Northfield, Bertram S. Adams, Hibbing, and Berton J. Branton, Willmar. The law provides that in case a claim involving controversial medical questions is allowed by the commission after the taking of testimony a medical board of three physicians from the panel of fifteen shall be chosen to act in the case. The panel includes ten physicians with experience in the diagnosis and treatment of industrial diseases and five x-ray specialists.

MONTANA

Personal—Dr. Lunsford D. Fricks has resigned as health officer of Helena and Lewis and Clark County because of poor health. His resignation was effective August 31. Dr. E. Martin Larson, Great Falls, was reelected president of the Montana Tuberculosis Association at its annual meeting, September 11. Mrs. Henriette Crockett, Helena, is executive secretary. Dr. Charles J. Bresee, Great Falls, has been appointed a member of the Montana Department of Public Health succeeding Dr. George F. Turman, Missoula, and Dr. Richard C. Monahan, Butte, has been named to succeed the late Dr. Enoch M. Porter, Great Falls.

NEW YORK

Cancer Programs—November 10 has been designated a cancer teaching day in Poughkeepsie, the program to be under the auspices of the Dutchess County Medical Society, the Dutchess County Tumor Clinic and the Tumor Clinic Association of the State of New York. The speakers will be Drs. Norman Treves, New York, on "The Management of the Patient with Advanced Cancer," Arthur J. Wallingford, Albany, "Cancer of the Uterus," and Maurice Lenz, New York, "The Treatment of Carcinoma of the Larynx." An evening session will be addressed by Drs. Lloyd F. Craver and Archie L. Dean, New York, on "The Significance of Enlarged Lymph Nodes," and "Carcinoma of the Genitourinary Tract" respectively. A cancer evening will be held at Olean, November 11, under the auspices of the Cattaraugus County Medical Society with Dr. Craver, on "The Role of the General Practitioner in the Early Diagnosis of Cancer" and Dr. Clyde L. Randall, Buffalo, on "The Significance and Management of Abnormal Vaginal Bleeding" as the speakers. The state medical society and the division of cancer control of the state department of health are sponsoring these programs.

New York City

Information Center on Alcoholism—The Research Council on the Problems of Alcohol, now located in Bronxville, N. Y., plans to open a New York Information Center to be located in the Grand Central district for information, without charge, regarding alcoholism and its treatment to alcoholic addicts and to all persons who have a problem connected with the use of alcohol. Family doctors, employers, clergymen, representatives of social agencies, educators and other civic leaders will be welcome at the center. A qualified man and woman will be on duty to provide information and lists of hospitals and private practitioners competent to treat alcoholism will be available. The council is also planning to move its office to New York.

Blood and Plasma Bank Established—The Blood Transfusion Association, formerly the Blood Transfusion Betterment Association, announces the establishment of a blood and dried plasma bank. Connected with the association's laboratory, the blood and dried plasma supply service is placed at the disposal of the community on an exchange basis and is available to hospitals as well as to individual physicians and welfare groups. The association will also continue its blood donor bureau service and continue to support blood research work in the field of transfusion and in the preventive application of the Rh factor in the blood transfusion of pregnant women. The laboratory and office of the Blood Transfusion Association provide twenty-four hour service at 2 West 106th Street.

Department of Tropical Medicine Created at Columbia—The establishment of a department in tropical medicine at Columbia-Presbyterian Medical Center has been announced. Dr. Harold W. Brown has resigned as dean of the School of Public Health of the University of North Carolina, Chapel Hill, effective January 1 to become the professor of parasitology under the new setup. He is also the first member of the faculty for training and research in tropical diseases, which will function under the immediate direction of the DeLamar Institute of Public Health, a division of the medical school. The project was made possible by a grant of \$150,000 from the Josiah Macy Jr. Foundation, which will also defray a concentrated five year program of research and teaching at the medical center (THE JOURNAL, Jan. 23, 1943, p. 271).

NORTH CAROLINA

New Division of Local Administration—The North Carolina State Board of Health has created a division of local administration and divided the state into three districts as a part of the general reorganization of the board. The directors of the districts will be Drs. Joseph C. Knox, Raleigh district 1, Robert E. Fox, Raleigh district 2 and John Roy Hege, Winston-Salem district 3. Because of the emphasis being placed on venereal disease control during the years preceding the war, and especially during this war period, it has been deemed advisable to consolidate all administrative activities pertaining to the cooperative working relationship between the state board of health and local health units, including venereal diseases, in the new division of local administration. Each district director will have under his immediate supervision certain personnel and services now provided by the state board of health consisting of a senior public health physician in venereal disease control, consultant public health nurses, a sanitary engineer, sanitary inspectors and public health educators. For the time being a skeleton organization of the present division of county health work will be retained in the division of local administration. An acting director of epidemiology will be responsible for the work of the division of epidemiology excluding venereal diseases. The office of personnel officer has been created to handle all questions between the state and local health units and the merit system council.

OHIO

Hospital News—The medical library of the late Dr. Orr A. Dickson Jefferson has been presented to the Ashtabula General Hospital, Ashtabula. The collection consists of six hundred volumes with publication dates running from 1896 to 1942.

Food Handlers to Be X-Rayed—The Gallia County Tuberculosis and Health Association is urging all food handlers and employees of food handlers and all owners of food establishments to request their employees to be tuberculin tested by the public health nurses. The association plans to bear the expense of this program and will urge all positive reactors to be X-rayed. All persons complying with this offer and found

to be free from communicable tuberculosis will be given health certificates. The Gallia County Association is said to be the first association in Ohio to inaugurate a testing program for food handlers, according to the *Bulletin* of the National Tuberculosis Association.

RHODE ISLAND

President of State Society Honored—Physicians and civic leaders from the Newport area gave a dinner recently in honor of Dr. Michael H. Sullivan, newly elected president of the Rhode Island Medical Society. Dr. Norman M. MacLeod, Newport, formerly president of the state society, was toastmaster at the dinner at which Dr. Sullivan was presented with an electric clock. Speakers included Superior Court Judge Mortimer A. Sullivan, Cornelius C. Moore, president of the city council, and Dr. Elihu S. Wing, Providence, president-elect of the state society.

Internship Reduction Disapproved by State Board—The Rhode Island Board of Examiners in Medicine announced that it does not approve a decrease in hospital internship from twelve to nine months for the duration of the war. At a recent meeting the board voted "that the licensing authority in this state would expect subsequent service in an army or navy station, field or general hospital for those physicians who were compelled by the military authorities to leave their regular internships after nine months of service. Physicians who are physically disqualified and who therefore do not enter the armed forces will be required to complete their usual twelve months of rotating internship." The board feels that this action will meet the military purpose of the proposal to reduce the internship without lowering the standards for licensure.

WASHINGTON

State Medical Election—Dr. Raymond L. Zech, Seattle, was named president-elect of the Washington State Medical Association at its annual meeting in September and Dr. Vernon W. Spickard, Seattle, was inducted into the presidency. Dr. Herbert E. Coe, Seattle, was chosen vice president.

Hospital News—Plans are going forward to construct the Doctors Hospital in Seattle at a cost of \$800,000. It will have 200 beds and will be sponsored by the King County Medical Service Corporation. The Franklin Delano Roosevelt Hospital at Bremerton has been built at a cost of \$986,000. The hospital was financed by the Federal Works Agency and was expected to be opened for patients on November 1.

Immunization Program—The Tacoma City Health Department and Pierce County Medical Society are cooperating in a community immunization program against diphtheria, smallpox and whooping cough. The decision to launch this program followed a request from the Tacoma housing authority to the health department for immunization services in the Salishan and Lincoln Heights areas. A survey showed that the number of children immunized was not enough to prevent occurrence of these diseases in epidemic proportions. The new program recommends that the family physician should encourage immunization of his own patients. It will include mass immunization clinics at the Salishan and Lincoln Heights areas by the city health department, with the department giving special emphasis to the promotion of immunization by the family physician in news releases.

WISCONSIN

Personal—Dr. William C. Keettel Jr., Madison, obstetric consultant for the Wisconsin State Board of Health, has been granted a leave of absence for service with the U. S. War Department. He has been assigned to a special project in Knoxville, Tenn., as chief of the division of obstetrics and gynecology, the *Quarterly Bulletin* of the state board of health reports.

State Medical Election—Dr. Charles Fidler, Milwaukee, was chosen president-elect of the State Medical Society of Wisconsin at its annual meeting in September and Dr. Russell M. Kurten, Racine, was installed as president. Mr. Charles H. Crownhart, Madison, is the executive secretary of the society. At the meeting Dr. Cornelius A. Harper, Madison, who recently retired as state health officer after many years of service, was presented with a scroll of appreciation in acknowledgment of his services.

HAWAII

Personal—Oscar A. Allen, Ph.D., professor of bacteriology and a former chairman of the department of botany at the University of Hawaii, Honolulu, has recently been named chairman of the newly established department of bacteriology, according to Science.

GENERAL

Dr MacLachern Named Chairman of Council on International Relations—Dr Malcolm I MacLachern, Chicago, is vice director of the American College of Surgeons, was named chairman of the Council on International Relations created by the forty-fifth annual convention of the American Hospital Association in Buffalo, September 12. The council will cooperate with Nelson Rockefeller, coordinator of the Office of Inter-American Affairs, and plans to assist in maintaining reciprocal relations with all hospital groups in the world (*THE JOURNAL*, September 25, p. 225).

Russian War Relief Requests Books—Dr Vladimir Ichedenko has requested the Russian War Relief, Inc., 11 East 55th Street, New York 16, to secure for Russian physicians a considerable number of medical textbooks, reference works and periodicals. Soviet institutions, according to Dr Ichedenko, are training two and one half times as many physicians as before the war. The shortage of paper and other material has greatly reduced Russian own publishing activities. Physicians who wish to contribute books may request a copy of the list by writing directly to the Russian War Relief.

American Therapeutic Society—The American Therapeutic Society will meet on November 15 at the Netherland Plaza Hotel, Cincinnati. Speakers will include:

- Dr. E. A. M. J. de Meijer, Cuba, The Therapeutic Value of the Fatty Acids of the Lecithins in Dermatitis
- Dr. Albert Wilbur Duse, New York, Vitamin C and Shock: Results of Recent Research Studies
- Dr. E. C. Harbison, Durham, N. C., Experience with Gonadotropic Therapy in Sterility
- Dr. Joseph B. Wolfe, Philadelphia, Renal Artery Thrombosis: Its Clinical Recognition and Management
- Dr. N. C. Mashburn, M. C., U. S. Army, Development of Aviation Medicine in the United States

Dr. Walter L. Vest, Huntington, W. Va., will deliver his presidential address on "William Shakespeare Therapist," at the annual banquet Monday evening.

Industrial Hygiene Meeting—The eighth annual meeting of the Industrial Hygiene Foundation will be held at the Mellon Institute, Pittsburgh, November 10-11. Included among the speakers will be:

- Charles I. Kettering, Dr. L. K. King, Dayton, Ohio, subject not announced
- Dr. Charles I. Kutcher, Pittsburgh, How the Inhalation of Some Chemicals Affects the Eye
- Lieut. Col. William J. McConnell, M. C., A. U. S. Surg., Robert H. Hann, U. S. Public Health Service, and Lieut. Col. Raymond Hussey, M. C., A. U. S., Recent Data on Health Hazards in War Industries
- Dr. Robert A. Kehoe and Edward J. Argent, Cincinnati, Fluorides as an Industrial Health Problem
- Dr. Oscar A. Sander, Milwaukee, Further Observations on Lung Changes in Electric Arc Welders
- Drs. Leroy L. Gardner and George W. Wright, Saratoga Lake, N. Y., Progress Report on a Study of Disability in Silicotics
- Dr. Clarence O. Sappington, Chicago, Health Problems of Women in Industry
- Dr. Edward J. Stieglitz, Washington, D. C., Health Problems of the Older Employee and Employer
- William M. Gaffner, Dr. Se., Bethesda, Md., Reducing Manpower Losses
- Philip Drinker, Ch. E., Boston, Control of Health Hazards in Ship Building, Including Welding
- Francis R. Holden, Ph. D., and W. C. L. Hemeon, M. S., Pittsburgh, Report on High Points of Foundation Plant Surveys
- Lieut. Col. Theodore I. Hatch, S. C., Fort Knox, Ky., Physiologic Effects of Heat
- Allen D. Brandt, D. Sc., sanitary engineer, U. S. Public Health Service, Application of Engineering Control Measures in Munitions Plant
- Theodore C. Waters, lawyer, Baltimore, Legal Developments in 1943 Respecting Industrial Health
- Almon E. Roth, Washington, D. C., Healthful Working Conditions Improve Labor Relations

Proposed School of Physical Therapy—A committee has been named to survey the field of physical therapy and to submit recommendations for the establishment of an institution of physical therapy for the study and teaching of the subject. The work will be financed with a grant of \$25,000 from Bernard M. Baruch, New York, who has been interested in the subject for many years and who wishes to set up such a project as a memorial to his father, the late Dr. Simon Baruch, professor of hydrotherapy, Columbia University College of Physicians and Surgeons, New York. Dr. Ray Lyman Wilbur, chancellor of Stanford University, has been named chairman of the committee, other members of which include Drs. Kristian G. Hansson, medical director of the Physical Therapy School at the Hospital for Special Surgery, New York, Carl R. Comstock, Saratoga Springs, N. Y., Benjamin A. Strickland Jr., lieutenant colonel, M. C., U. S. Army, Tucson, Ariz., Charles F. Behrens, commander (MC), U. S. Navy, head of the x-ray department, Naval Medical Center, Bethesda, Md., John S. Coulter, medical director of the Physical Therapy School at

Northwestern University, Chicago, Dr. Frank H. Kruser, medical director of the Mayo Clinic Department and School of Physical Therapy, Rochester, Minn., and William T. Sanger, Lt. D., president of the Medical College of Virginia, Richmond.

Southern Medical Association—On November 16-18 the Southern Medical Association will hold its annual session in Cincinnati at the Netherland Plaza Hotel, with the Campbell-Kenton County Medical Society of Kentucky and the Academy of Medicine of Cincinnati acting as hosts. This is the first time the Southern Medical Association has met north of the Mason-Dixon line. At a general public session Tuesday night Dr. Tom D. Spies, Birmingham, Ala., and Cincinnati, will be presented with the Research Medal of the association "in recognition of his outstanding contributions to our knowledge of the science of human nutrition, especially in his elucidation of the earlier and better methods of diagnosis and treatment of disease." Other speakers at this session will include Dr. Harvey I. Garrison, Jackson, Miss., president of the association, on "The Nation's Most Valuable Asset and Its Greatest Problem." The general program includes the following speakers:

- Norman T. Kirk, surgeon general of the U. S. Army, The Care of Battle Casualties and the Casual Sick
- Dr. James F. Paulin, Atlanta, Ga., President, American Medical Association, The Future of American Medicine
- Dr. James W. Bruce, Louisville, Free Diet in Juvenile Diabetes
- Dr. J. Wallace Frank, Louisville, Surgical Treatment of Cancer of Uterine Body in the Obese
- Dr. Walter Dean, Louisville, Otitis Media Still Takes Its Toll
- Dr. William A. Altmeier, Cincinnati, Penicillin in Surgery
- Dr. S. Spafford Ackerly, Louisville, Is There An Anxiety Component of Every Complaint?
- Dr. Nathan Chandler Foot, New York, Glandular Metaplasia of the Epithelium of the Urinary Tract
- Comdr. Edward L. Bortz (MC), U. S. Naval Reserve, New Horizons in Medicine
- Dr. Bernard H. Nichols, Cleveland, The Elevation of Excretory Urography in General Practice
- Major Archibald Fine and Lieut. Theodore B. Steinhausen, M. C., U. S. Chest Lesions in Ninety Thousand Prospective Aviation Cadets
- Drs. Hugo T. Engelhardt and Vincent deP. J. Derbes, New Orleans, Allergies to Liver Extract
- Thomas Parran, surgeon general, U. S. Public Health Service, Health Problems Ahead
- Dr. Louis A. Bunc, Rochester, Minn., Jeep Disease (Pilonidal Disease of Mechanized Warfare)
- Dr. Harold H. Kuhn, Durham, N. C., Degenerative Fibrosis with Neuromatous Proliferation of Plantar Nerve (Morton's Metatarsalgia)
- Dr. Paul H. Holinger, Chicago, Post Thyroidectomy Laryngeal Paralysis: Medical and Surgical Aspects
- Dr. Edward H. Carr, Dallas, Texas, Ocular Headaches

The section on medical education and hospital training will offer the following program on Tuesday:

- Dr. Frank R. Bradley, St. Louis, Education of the House Staff Now and After the War
- Colonel James R. McDowell, M. C., U. S. Army, Postgraduate Training in Army Air Force Hospitals
- Dr. Stanley E. Dorst, Cincinnati, The Effect of the Accelerated Program on Faculty and Students After an Experience of Eighteen Months
- Lieut. Col. Earl H. Perry, M. C., U. S. Army retired, The Student's Army Specialized Training Program in Action
- Lieut. Col. Rittig Arnold Griswold, M. C., A. U. S., The Function of the Service Command Consulting Surgeon

Other groups meeting during the session of the Southern Medical Association include the American Academy of Pediatrics, region 2, and the American Public Health Association southern branch, which will hold only a luncheon meeting of the governing council this year.

FOREIGN

Personal—The American Bureau for Medical Aid to China announced on October 8 the safe arrival at Calcutta of four medical specialists who are returning to China under its auspices. Miss Evelyn Lin, who will be superintendent of nurses at the National Central University Medical School at Chengtu, Miss Hui-yn Wang, who will be director of public health nursing in Szechuan Province, Dr. Y. K. Wu, who will specialize in chest surgery at the Central Hospital in Kweiyang, and C. S. Hsueh, public health statistician, who will join the staff of the National Institute of Health at Chungking.

Deaths in Other Countries

Dr. Cecil Rowntree, vice president of the International Cancer Union, died on October 14 at his home, Little Warren, East Grinstead, Sussex, aged 63. He was educated at the University College, London, and had served as Hunterian professor of surgery at the Royal College of Surgeons of England. Dr. Rowntree was consulting surgeon to the Royal Cancer Hospital and emeritus surgeon to the Woolwich Memorial Hospital. He was also chairman of the Westminster Division of the British Medical Association and a fellow of the British Association of Surgeons.

The Proposed National Medical Service The Government's Proposals

The objections of the medical profession to certain features of the government scheme for a comprehensive medical service have been stated in previous letters. An address by Mr Ernest Brown minister of health to the annual meeting of the Association of Welsh Insurance Committees is of unusual importance as it deals with some of these objections and also discloses the government's proposals more fully than has been done before. He stated that when these were published the fullest opportunity would be given for discussion by the medical profession, local government and the public. Criticism could then be based—for the first time—on full knowledge of what the government has in mind. The first aim must be to cut down some of the limitations on the present service, so that people can get consultant specialist, hospital and convalescent treatment, Mr Brown said. The scheme must aim at prevention as well as cure. In spite of statements to the contrary, the minister stated, it was the avowed intention of the government to preserve the important principle of free choice of doctor and clinical freedom of the doctor in treatment. He hoped that the scheme would secure a fuller service of practitioners in congested areas where they were now insufficient. The service would be based on the family as a unit and the general practitioner as its primary attendant. Yet it had been alleged that the government wanted to abolish the family doctor. What was wanted, he said, was to provide a family doctor for millions for whom one was not now available.

Nearly two years ago the government announced its intention of coordinating the voluntary and municipal hospital systems. The new health service, it was explained, would render possible a completely integrated medical service, starting from the family doctor and embracing all institutional services. This would also make available to doctors a full consultant and specialist service from the hospitals. The government also hoped to give the general practitioner a better service for post-graduate courses, so that he could keep abreast of modern developments. Perhaps even more important, the government must see that he had the opportunity for leisure to get the best possible advantage from these courses.

Changes at the Royal College of Surgeons

At a meeting of the fellows of the Royal College of Surgeons the president, Sir Alfred Webb-Johnson, reviewed important recent changes. The primary examination for the fellowship has been made entirely postgraduate, with pathology introduced as an additional subject to anatomy and applied physiology. The interval between graduation and entry for the final examination is now two years. The damage done by bombing to the Royal Colleges of Physicians and Surgeons opened the question of the three Royal Colleges (the third being the College of Obstetricians and Gynecologists) working together in a combined building or in adjacent buildings. The present site of the Royal College of Surgeons had great advantages for such a building. The value of the buildings still standing was estimated at \$1 000 000. The president reported the definite view of the council that there must be a portal to the medical profession under the sole control of a professional body, and therefore the council disagreed with the suggestion that a university degree should be a sine qua non for medical qualification.

THE BEVERIDGE SCHEME

A representative committee of the medical profession, the president reported, was discussing the Beveridge scheme with the minister of health. The Royal Colleges were represented by their president, and he had insisted that he must be regarded as representative of consultant surgery. For this purpose the Royal Colleges had held a conference of representatives from all centers in order to obtain the views of all consultants throughout the country. They maintained that some freedom must be left both to doctor and to patient and declined to countenance the conversion of a free profession into a public service. An individual must be left free to enter the medical profession and to practice, they held. The profession must have a large say in the organization and management of the national health service. The administrative structure must allow a generous representation of the profession. The health service must be comprehensive, and the local health authorities as at present constituted did not provide satisfactory areas for dealing with the needs of the population. Some scheme of regionalization was essential. The government declared its intention that opportunities for private practice should be maintained, and the most reasonable way of providing for this seemed to be to apply the national contributory scheme only to those who needed such provision. In planning for positive health and the prevention of disease, the nonmedical proposals of the scheme—particularly improved housing avoidance of unemployment, children's allowances, disability pay and old age pensions—were more important than revolutionary changes in medical practice.

A Practical Application of the Discovery of the Rh Factor

In a circular to local health authorities, the Ministry of Health points out a practical application of the discovery in 1940 by an American scientist that 85 per cent of the American and British white population have a previously unrecognized factor in their red corpuscles. As it was also found in the rhesus monkey it is called the Rh factor. A particular variety of jaundice and anemia has been known to occur in infants for some years. It seems to run in families, and often several infants in one family are affected. Some are stillborn, and others live only a short time. It has been found that these jaundiced infants nearly always have the Rh factor in their red cells, but their mothers are Rh negative. The infants have been jaundiced and anemic because before birth their red cells have passed into the mother's circulation, where antibodies to the Rh positive cells have developed and passed back into the infant's blood, destroying its red cells. If, however, the infant is given a blood transfusion with Rh negative blood, these antibodies are soon destroyed and its life is saved. If the mother should need blood transfusion after the infant is born, it has been found that she should also receive Rh negative blood.

A Film of Surgery in Chest Disease

A remarkable film entitled *Surgery in Chest Disease* has been shown at a London theater to a distinguished medical audience. It is the first of a series of medical films to be made for the British council and is primarily intended for overseas medical audiences. Surgeon Rear Admiral Gordon Gordon-Taylor, a member of the medical panel of the British Council said that the film had been made by Gaumont-British Instructional with the cooperation of medical resident medical and auxiliary staffs of the Brompton Hospital for Diseases of the Chest where most of the scenes were taken. The general purpose of the film is to show the scope and progress of chest surgery in Britain. Its climax is an operation for total removal of a lung affected with cancer an operation performed for the first time only ten years ago one which even now can be undertaken only by a few surgeons of special ability.

Results of Blood Cultures in Pemphigus Foliaceus

As reported in a previous letter (*THE JOURNAL*, Jan. 23, 1943, p. 276) many cases of a malignant type of pemphigus foliaceus (fogo selvagem or wild fire) have occurred and continue to occur in the rural areas of the central states of Brazil and in the neighboring regions of Paraguay and Bolivia as well. The main focus of the disease is the state of São Paulo where hundreds of cases are already known and where a special service has been organized to combat the disease. This service under the direction of Dr. J. P. Vieira has a hospital, several outpatient clinics and visiting doctors. The cause of the disease is still unsolved, even its infectivity and its content or nature are subjected to much discussion. Dr. J. Aranha Campos, assistant director of the São Paulo service, has published a study of the results of blood cultures from 600 cases during the febrile stage of the disease. The culture medium used was glucose broth with liquid petrolatum in 7:6 in tubes of 10 cc. Equal parts of blood and culture medium were mixed. In 139 of these cases with temperature of 39°C (102.2°F) and above streptococci mostly of the hemolytic type, were found in pure culture. As controls, Dr. Campos made blood cultures from all other patients without fever or subjected to artificial fever and these cultures were always negative or were positive only for *Staphylococcus albus*. The patients were divided into five groups according to the severity of the disease. The fever is rare in patients with slight symptoms or in the regressive stage of the disease. But the feverish spells are frequent in patients with generalized cutaneous lesions. The fatal cases present several of these feverish spells in the last stage of the illness. The author emphasizes the close relationship between the streptococcal bacteremia and the fever spells and the spread of the bullous cutaneous lesions. The high hospital fatality rate of the disease (about 40 per cent) is explained by Dr. Campos as the effect of the streptococcal toxemia, which coincides with the final diarrhea and hyperpyrexia. In the patients subjected to artificial fever the general condition is not modified, and spread of bullous dermatitis does not occur. Dr. Campos concludes that the hemolytic streptococcus is probably the cause of the disease.

Cancer and Race

Some time ago Dr. Joaquim E. de Alencar published the first part of a study on the epidemiology of cancer in Brazil, the main features of which have been reported in a previous letter (*THE JOURNAL*, June 12, p. 459). In a new paper he presents the mortality from cancer in Rio de Janeiro according to races and nationalities. As the composition of the city population is not known in relation to color, because this kind of information has never been included in the censuses, and as the information regarding the nationalities would have to be derived from the last census, which was taken in 1920, Dr. Alencar decided to study the trend of mortality from 1903 to 1941, not as specific death rates for each color or nationality, but as a ratio between the absolute number of deaths from cancer to the absolute number of deaths from all causes, in each specific group of population. During the thirty-nine years included in the study the ratio of deaths from cancer to the deaths from all causes in the general population has risen steadily from 0.0013 in 1903-1905 to 0.0036 in 1939-1941, which corresponds to an increase of 174 per cent. The increase has been greater for the white than for the colored people: 201 per cent for the white, 161 per cent for the mulatto and 127 per cent for the Negro.

The differences in the increase of a similar ratio for the several nationalities into which the population is divided in the Brazilian statistical returns present interesting facts. The average increase of 174 per cent for the general population is differentiated as follows for the various nationalities: Brazilian 187 per cent, Portuguese 213, Italian 115, Spanish 310, German 306, English and Anglo-American 400, other European 149 and Asiatic (mainly Syrian) 385. It is not easy to grasp the complete significance of these figures, but Dr. Alencar points out the larger increase of the ratio in the population of European descent, particularly Nordic, a fact similar to the higher death rates shown by him in the first part of his study for the southern Brazilian cities where the amount of people of European descent is larger. It is interesting to recall, from the first part of the study, the increasing trend of the mortality from cancer in Rio de Janeiro since the beginning of the century: 33.8 per hundred thousand in 1902-1911, 41.7 in 1912-1921, 45.9 in 1922-1931 and 55.2 in 1932-1941. For the last five years, 1938-1942, the progression of the cancer death rate has been 55.0, 59.0, 65.3, 66.4 and 67.3.

Healthy Carriers of *Endameba histolytica* Cysts

Dr. A. Franco do Amaral from the Department of Parasitology of the University of São Paulo, and Dr. C. Avila Pires, physician of the penitentiary of the state of São Paulo, report the results of a survey in a sample of 300 inmates of the penitentiary to study the incidence of *Endameba histolytica* cysts in healthy persons. All the individuals examined were apparently in good health at the moment of the examination. The examinations have been made by the Faust zinc sulfate centrifugal flotation method. As far as the authors are aware it is the first time this method has been used for an extensive survey in Brazil. The individuals in the sample were subjected to a series of successive examinations, positive carriers having been found even in the fifth examination. Only the sixth examination showed no more cyst passers. The examinations were performed for each person during a period of twenty days with the hope of obtaining a fecal specimen corresponding to a stage of maximum production of cysts. Of the total of 300 persons examined 118 were positive for cysts in the total of five examinations (39.3 per cent). The first examination showed 64 positive results (21.3 per cent), the second 24 (8.0 per cent), the third 17 (5.6 per cent), the fourth 10 (3.3 per cent), the fifth 3 (1.0 per cent) and the sixth none. The large majority of the positive carriers were agricultural laborers from scattered districts of the state. The very good hygienic conditions of the penitentiary led the authors to exclude the possibility of the infection having been contracted at the institution. Such a high incidence of cysts carriers, as compared with that observed in other countries where the same method has been employed, suggests its use to survey other groups of healthy persons in Brazil in order to furnish a basis for estimating the real significance of amebiasis in the country.

Marriages

GEORGE E. ROULHAC, Florence, Ala., to Miss Polly Ann Billington of Franklin, Tenn., near Oran, Algiers, North Africa, October 2.

HERBERT RICHARDSON DOWE, Columbia, S. C., to Miss Jewel Gwendolyn Rhinehart of Leesville, September 9.

TOM JERRY SMITH, Covington, Ky., to Miss Martha Geraldine Allen of St. James, Mo., in August.

LYMAN DAVID HEIM, Schuylkill Haven, Pa., to Miss Lulu Longenberger of Nuremberg in August.

FRANK S. CROSS, Lansing, Mich., to Miss Mary Charlotte Keith of Chicago, June 29.

ALBERT EDEN CREMER, St. Louis, to Miss Evelyn Edith Kline of Columbia, S. C., in July.

Deaths

Joseph Milton Heller * Washington D C, Georgetown University School of Medicine, Washington 1896 an Affiliate Fellow of the American Medical Association, assistant demonstrator of anatomy at his alma mater from 1897 to 1898, professor of tropical medicine at the George Washington University School of Medicine from 1904 to 1910, dispensary staff member at the Emergency and Garfield hospitals from 1896 to 1898, veteran of the Spanish-American War, Philippine Insurrection and World War I in charge of supply of water in Manila during cholera epidemic in 1902 and received commendation by the late President William Howard Taft, then governor general of the Philippines, commissioned major in the medical reserve corps of the U S Army in 1917 later served as division sanitary inspector and acting chief surgeon of the 90th division commanding officer of Base Hospital at Fort Riley, Kan, General Hospital number 23, Hot Springs, N C, and number 22 in Philadelphia lieutenant colonel in the medical corps of the U S Army from 1918 to 1922, colonel in the medical reserve corps not on active duty participated in General Lawton's advance in northern Luzon and surgeon of Major Batchelor's "Lost Battalion" recommended for Congressional Medal of Honor in 1915 received Silver Star citation from the President of the United States for attending wounded under fire, Battle of Naguilian, Luzon, Dec 7, 1899, since 1938 surgeon general of the Military Order of the World War, for many years national secretary of the Carabao, organization of officers who served in the Philippines member of the Military Order of Foreign Wars Military and Naval Order of the Spanish American War and the Association of Military Surgeons of the United States died in the Naval Hospital National Naval Medical Center Bethesda, Md, October 11, aged 71, of coronary artery disease

George C Chene, Detroit, Detroit College of Medicine 1905, member of the Michigan State Medical Society and the Radiological Society of North America past president of the Detroit Roentgen Ray and Radium Society curator of the museum and clinical assistant in gynecology at his alma mater from 1908 to 1910, clinical assistant in gynecology in 1911 clinical assistant in roentgenology from 1911 to 1913 assistant clinical professor of roentgenology from 1913 to 1918 professor and head of roentgenology from 1918 to 1920 and assistant professor of roentgenology, 1920-1921, established the first x-ray laboratories at St Mary's and Providence hospitals in Detroit and at the Hotel Dieu Hospital in Windsor, Ont Canada his retirement from active duty at the Providence Hospital was marked by the staff with a public banquet at which he was the recipient of an honor plaque for long and faithful service, secretary of the hospital staff for many years, staff member of St Mary's Receiving, Eloise and Providence hospitals either as attending or as consulting radiologist died in the Harper Hospital August 31 aged 61, of carcinoma of the tongue and throat

Peter Whitman Rowland, University Miss, Memphis (Tenn) Hospital Medical College 1882 professor of pharmacology at the University of Mississippi School of Medicine member and past president of the Mississippi State Medical Association and the Mid South Post Graduate Medical Assembly fellow of the American College of Physicians, contract surgeon University of Mississippi Student Army Training Corps during World War I, reported to be first physician to administer oxygen through the nose tube in the treatment of pneumonia using the device on a patient in 1903, the medical library at the University of Mississippi was named in his honor in 1939, two years previously he volunteered his services to augment the library and became field director on the staff of the Bramlett Hospital Oxford died in Oxford, October 14, aged 82 of coronary thrombosis

Edmund Pendleton Shelby * Sarasota Fla University of the City of New York Medical Department 1891 clinical professor of medicine at the University and Bellevue Hospital Medical College New York from 1918 to 1934 formerly instructor in pharmacology and therapeutics at the Cornell University New York for many years on the staff of the New York City Hospital past president of the New York Pathologic Society and the West End Medical Society formerly chairman of the section on medicine of the New York Academy of Medicine fellow of the American College of Physicians consultant in medicine at the Florida Medical Center Venice author of "Hodgkin's Disease," 1907 and "Balancing the Physiological Budget" in *Hypatia* 1936 died in Lexington Ky September 22 aged 76 of carcinoma

Charles P Arzt, St Paul University of Minnesota College of Medicine and Surgery, Minneapolis, 1895, died July 29, aged 73, of ventricular fibrillation

Alfred Goodrich Bailey, Berkeley, Calif, Homeopathic Hospital College, Cleveland, 1889, died August 22, aged 76, of tuberculosis and nephritis

Elizabeth Ethel Bowen, Lincoln Park, N J Woman's Medical College of Pennsylvania, Philadelphia, 1907, died August 4, aged 61, of heart disease and multiple myeloma

Arnold Louis Brandt * Pacific Beach, Wash Washington University School of Medicine, St Louis, 1902, formerly associated with the Indian Service, died in the Barnes Hospital, St Louis, July 5, aged 66 of retroperitoneal hemorrhage due to ruptured aneurysm of the abdominal aorta

Mills C Brasher, Linden, Ind, Bennett College of Eclectic Medicine and Surgery, Chicago, 1889, on the staff of Culver Hospital, Crawfordsville, where he died August 13, aged 78, of appendicitis gallstones and peritonitis

John Joseph Brennan, Worcester, Mass, Harvard Medical School, Boston 1886, member of the Massachusetts Medical Society, in 1937 was presented with a scroll commemorating fifty years' membership in the Worcester District Medical Society, on the staffs of the Worcester City Hospital and St Vincent Hospital, where he died August 26, aged 79, of arteriosclerosis

John L Brown, Campbell, Mo, St Louis College of Physicians and Surgeons 1890, member of the Missouri State Medical Association, died in the Poplar Bluff Hospital, July 2, aged 73, of chronic myocarditis

John W Brown, Jefferson Township Ind Hospital College of Medicine, Louisville, Ky, 1881, died July 10, aged 91, of cerebral hemorrhage

Mabel Margaret Wirt Butka, Pomona, Calif College of Medical Evangelists, Loma Linda and Los Angeles, 1918, on the staff of the Pomona Valley Hospital, died in La Verne August 22, aged 48, of accidental carbon monoxide poisoning

Malcolm Samuel Campbell, Malvern, Iowa Tufts College Medical School, Boston 1915 served one month on the staff of the Binghamton (N Y) State Hospital as resident in psychiatry died in Binghamton August 7, aged 52, of subdural hematoma

William Price Connally, McGregor Texas Medical Department of Tulane University of Louisiana, New Orleans, 1898 a captain in the medical corps of the U S Army during World War I, died in a Waco hospital July 11, aged 72, of cerebral hemorrhage

Isaac Gladstone Cook, St Louis, St Louis College of Physicians and Surgeons 1911, served during World War I, died in the Veterans Administration Facility, Jefferson Barracks, August 8, aged 69 of bronchopneumonia

Lucy Gusta Coon * Sterling Ill State University of Iowa College of Medicine Iowa City 1927 medical adviser for women at the University of Illinois Urbana, from 1936 to February 1943 and since the latter date in a defense plant at Dixon died in the Grant Hospital, Chicago, August 29 aged 47 of pulmonary embolism

Louis Leopold Davidson, Newark N J University of Vermont College of Medicine Burlington 1902, Cornell University Medical College, New York, 1903 member of the Medical Society of New Jersey, also a lawyer, formerly coroner of Essex County a director of the Lincoln National Bank on the staff of the Newark Beth Israel Hospital, where he died August 28, aged 63 of cerebral hemorrhage

Benjamin Lawrence Dorsey, Los Angeles Marions-Sims College of Medicine St Louis 1896 Barnes Medical College St Louis 1899 formerly professor of gynecology at the Barnes Medical College died in Guadalajara Mexico August 2 aged 73 of acute enterocolitis

John William Eckstein, Ryan Iowa Northwestern University Medical School Chicago 1916 served in France and as a first lieutenant in the medical corps of the U S Army during World War I died in the Veterans Administration Facility, Des Moines August 7 aged 53 of lobar pneumonia

Walter Brownley Foster, Richmond Va Medical College of Virginia Richmond 1901 associate public health physician for the Virginia Department of Health since 1940 director of public welfare for the city of Richmond from 1924 to 1940 organized the city health department in Roanoke and served as health officer from 1910 to 1924 past president of the Roanoke Academy of Medicine and a member of the governing council of the American Public Health Association died August 10 aged 65 of coronary thrombosis

Frank Harrold Grandy # Seattle, Indiana University School of Medicine 1926, died August 15, aged 45, of hypertension and cerebral hemorrhage.

William Walter Grantier, Buffalo, University of Buffalo School of Medicine 1899, died August 8, aged 67, of chronic myocarditis, arteriosclerosis and cerebral hemorrhage.

Richard Watson Graves, Arlington, Texas, University of Louisville (Ky.) Medical Department, 1883, died August 5, aged 85, of senility.

Samuel Thomas Gray # Albia Iowa State University of Iowa College of Medicine Iowa City, 1889, died in Wichita, Kan. August 12, aged 77, of uremia.

Charles Gregory Griffin Miami Fla. University of Nashville (Tenn.) Medical Department 1908, member of the Florida Medical Association, died in Nashville, Tenn. August 31, aged 60, of coronary occlusion.

Archer Thomas Hampton, Oilwood, Texas, Southern Methodist University Medical Department Dallas 1913, member of the State Medical Association of Texas, chairman of the governing board of the Orphans Home at Corsicana and the Old Folks Home at Lums, died July 7, aged 59, of coronary thrombosis.

George Wesley Horrom, Rolla, Mo., Medical College of Indiana Indianapolis 1894, member of the Missouri State Medical Association, past president of the Phelps-Crawford Counties Medical Society, died July 10, aged 73, of cerebral hemorrhage.

Andrew Richard Johnson, Isanti, Minn., University of Minnesota Medical School Minneapolis 1929, member of the Minnesota State Medical Association, on the staff of the Ashbury Hospital Minneapolis, where he died July 25, aged 44, of pulmonary embolism following an appendectomy.

Frederick Marshman Kennison, Boston, Tufts College Medical School Boston 1905, member of the Massachusetts Medical Society, died suddenly July 31, aged 80.

James Oscar Meade, Mendota, Va., Tennessee Medical College Knoxville 1898, member of the Medical Society of Virginia, died July 17, aged 70, of hypertension and thrombosis.

John William Montrose, Grass Valley, Calif., Bellevue Hospital Medical College New York, 1892, died in Stockton, July 26, aged 84, of senility.

James T. Myers # Hotchkiss, Colo., University Medical College of Kansas City, Mo., 1894, served as health officer, died July 28, aged 75, of cerebral hemorrhage.

William Frederick Nienstedt, Hartford, Kan., College of Physicians and Surgeons, Medical Department Kansas City University, Kansas City 1898, member of the Kansas Medical Society, died in the Newman Memorial County Hospital, Emporia, July 6, aged 67, of coronary thrombosis and sclerosis.

Albert Sidney Oburn # Altoona, Pa., Jefferson Medical College of Philadelphia, 1896, a member of the exemption board during World War I and recently a member of the induction board, a director of the Blair County Tuberculosis Society, chief of the medical staff of the Altoona Hospital, died August 9, aged 68, of coronary occlusion.

Richard John O'Connell, Chicago, Rush Medical College, Chicago, 1899, formerly instructor in medicine at the Loyola University School of Medicine for many years on the staffs of St. Joseph's and West Side hospitals, Chicago, and St. Francis Hospital, Evanston, Ill., where he died August 22, aged 74, of auricular fibrillation and chronic myocarditis.

Frederick Strattnor Orem # Baltimore, University of Maryland School of Medicine, Baltimore, 1900, associate in pediatrics at his alma mater, on the dispensary staff of the University Hospital, where he died August 8, aged 70, of nephritis.

Horace M. Paynter, Salem, Ind., University of Louisville (Ky.) Medical Department, 1890, died August 18, aged 77, of cerebral hemorrhage, hypertension and diabetes mellitus.

Thomas H. Pope # Newberry, S. C., Medical College of the State of South Carolina, Charleston, 1908, past president of the Newberry County Medical Society, member of the board of trustees of his alma mater, member of the District Advisory Medical Board of Selective Service, died August 6, aged 67, of coronary occlusion and hypertension.

Francis M. Roberts, Jacksonville, Ill., Cincinnati College of Medicine and Surgery, 1900, member of the Illinois State Medical Society, formerly postmaster and member of the school board of Lynnville, served three terms as mayor of Chapin and several terms as member of the school board, at one time superintendent of the Morgan County Tuberculosis Sanatorium

"Oaklawn", on the staffs of Our Saviour's Hospital and the Passavant Memorial Hospital, where he died August 6, aged 73, of cerebral hemorrhage.

Allen Charles Tiffany, Mackinaw City, Mich., Detroit College of Medicine and Surgery, 1914, served overseas and is a major in the medical corps of the U. S. Army during World War I, major in the medical reserve corps not on active duty, served on the city council for a number of years, on the courtesy staff of the Little Traverse Hospital, Petoskey, where he died August 10, aged 63, of coronary and cerebral arteriosclerosis and hypertension.

Juan Arango Villegas, Cliffside Park, N. J., Jefferson Medical College of Philadelphia, 1929, member of the Medical Society of New Jersey, school physician for Cliffside Park and formerly at Fairview, on the staffs of Holy Name Hospital, Tenck, Englewood Hospital and North Hudson Hospital, Weehawken, died in the Medical Center of Jersey City August 18, aged 41, of pneumonia.

William Desmond Wagar, Michigan, N. D., University of Minnesota College of Medicine and Surgery, Minneapolis, 1898, member of the North Dakota State Medical Association, for many years mayor, died in Kingston, Ont., Canada, July 23, aged 68, of carcinoma.

Bruce Courtney M. Whyte # Battle Creek, Mich., Trinity Medical College, Toronto, Ont., Canada, 1904, formerly on the staff of the Battle Creek Sanitarium, on the staff of the Community Hospital, where he died August 17, aged 64, of carcinoma of the stomach and myocardial insufficiency.

DIED WHILE IN MILITARY SERVICE

William Morgan Chew, New York, University of Virginia Department of Medicine, Charlottesville, 1931, member of the Medical Society of the State of New York and the American Academy of Ophthalmology and Otolaryngology, specialist certified by the American Board of Otolaryngology, formerly a member of the staffs of Bellevue and St. Luke's hospitals, entered the medical corps of the U. S. Naval Reserve as a lieutenant commander on June 24, 1942, died in the Johns Hopkins Hospital, Baltimore, September 4, aged 39.

Hugh Beauregard Disharoon # Lieutenant Colonel, M. C., U. S. Army, Lewisburg, Tenn., Vanderbilt University School of Medicine, Nashville, 1935, appointed a lieutenant in the medical reserve corps of the U. S. Army on June 12, 1935 and began active duty in the medical corps of the regular Army on July 1, 1940, assigned to the Fitzsimons General Hospital, Denver, rose through the various ranks to that of lieutenant colonel on Jan. 15, 1943, died in the Station Hospital, Fort Benning, Ga., August 22, aged 32, of virus pneumonia.

John Deetz Houck, Scranton, Pa., Harvard Medical School, Boston, 1941, appointed a lieutenant in the medical corps, Army of the United States, April 23, 1942, began active duty Aug. 1, 1942, attached to the 407th Infantry, Camp Maxey, Texas, later commissioned a captain, died in the O'Reilly General Hospital, Springfield, Mo., October 3, aged 27, of cerebral edema due to brain tumor of the left frontal lobe.

Thomas Lacy Morrow # Medical Director, Captain, U. S. Navy, Mebane, N. C., University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1915, appointed an assistant surgeon in the U. S. Naval Reserve, April 10, 1917 and on June 23, 1917 a lieutenant (jg) in the medical corps of the U. S. Navy, advanced to the rank of captain in July 1941, served aboard the U. S. S. *Nero*, *Eurona*, *Patoka* and *Tulsa*, served at the Naval Base, Cardiff, Wales, with the Destroyer Force, the Atlantic Fleet, at the Naval Hospital, and the Pharmacist's Mates' School, Norfolk, Va., the Marine Barracks and Naval Hospital at Parris Island, S. C., the Naval Hospital, Boston, and on the Asiatic Station, fellow of the American College of Surgeons, awarded a letter of commendation for his work as head of the Medical Relief Unit at Belize, British Honduras, after the hurricane of September 1931 and the medal of distinction by the president of Nicaragua for services rendered in that country from May 1931 until November 1932 as brigade surgeon, second brigade of marines, died at Guilford College, N. C., August 11, aged 54, of cerebral hemorrhage, while on leave from his post of duty at the Naval Hospital, Marine Barracks, New River, N. C.

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act and are designated C N J. The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Ambrosia Tightener—Hinz Ambrosia Inc New York Shipped between Dec 6 1940 and Jan 3 1941 Composition an astringent consisting essentially of alcohol, water, zinc phenolsulfonate and perfume. Misbranded because of the following false and misleading representations on label and in accompanying circular: Tightener for large pores, wrinkles, oiliness. Tends to prevent the enlargement of pores. It is especially useful to lessen oiliness and aids in clearing up pimples and muddy complexions resulting from external causes. Stimulates the skin. Ambrosia cream contains ingredients that resemble the natural sebaceous oils and fats of the human skin. It helps to make dry skin smooth and thus aids in removing the annoying tiny lines caused by skin dryness. —[C N J F D C 84 February 1943]

Camelline—Walter M Willett San Francisco Shipped Aug 28, 1941 Composition essentially calcium carbonate bismuth subcarbonate alcohol and water. Misbranded because circular accompanying package falsely represented that this product when used as directed was a natural aid to beauty and greater charm would keep the skin delicate and youthful, would preserve the youthful creamy appearance of the skin was a stimulating lotion, would protect the skin against wind and sun was beauty and youth, would protect the face against the ravages of weather and prevent the disagreeable effects of exposure to the sun and wind. —[C N J F D C 85 February 1943] This product was also misbranded under the provisions of the law applicable to drugs.

Chin Firm—Burtley Company New York Shipped between April 1 and 11, 1941 Composition essentially a clay with water and perfume. Misbranded because of false and misleading representations that this product would produce a firm chin and throat line besides correcting crows feet. —[C N J F D C 87 February 1943]

Chin Up—L R Kallman and Company Chicago Shipped June 3 1941 Composition 53.4 per cent of alcohol with tannic acid water and perfume. Misbranded because it contained a larger amount of alcohol than the 39 per cent declared on the label. Further misbranded because label falsely represented that the use of this product would result in elimination of crepey skin or flabby tissues of neck or skin. —[C N J F D C 88 February 1943]

La Bonita Hollywood Skin Stimulant and La Bonita Hollywood Texture Oil—House of Hollywood Los Angeles Shipped May 2, 1941 Composition not reported. The first named was misbranded because its designation falsely represented that the product contained some ingredient capable of stimulating the skin. The second was misbranded because of the misleading term Texture Oil in its name and because the directions for use gave the false impression that this preparation would affect the structure of the skin whereas it would not. —[C N J F D C 86 February 1943]

Natone Natural Oil for the Hair—J D Bentley Los Angeles Shipped June 20, 1941 Composition essentially saponifiable and unsaponifiable fats perfume, water and a small amount of phenol. Misbranded because label falsely represented that this product would promote the growth of hair, since it did not contain any ingredient capable of producing that result. —[C N J F D C 89 February 1943]

S T D 'The' Hair Tonic—George A Dustin Chicago Shipped Dec 17 1941 Composition essentially small amounts of potassium arsenite, sodium borate and water. The potassium arsenite contained arsenic equal to 0.2 gram per hundred cubic centimeters. Misbranded because of the following false and misleading statements in labeling: Stops the dandruff. The Hair Tonic for dandruff falling hair itching scalp and all scalp ailments. Wet scalp with Ess Tee-Dee Hair Tonic and massage every day until scalp is free from dandruff. For best results shampoo the hair once each week then apply Ess Tee-Dee Hair Tonic after hair has dried and continue applications every third or fourth day until scalp is free from dandruff and then use Tonic only as often as it is necessary to keep the scalp in a clean and healthy condition. The Hair Tonic. —[C N J F D C 90 February 1943] The product was also declared misbranded under the provisions of the law applicable to drugs.

DANGEROUS TO HEALTH

Because of Inadequate Warnings on Labels

[EDITORIAL NOTE—These abstracts differ from other abstracts of Notices of Judgment issued by the Food and Drug Administration of the Federal Security Agency which have appeared in these pages in that they deal with nostrums which were misbranded because their labels failed to carry adequate warnings against giving them to children or using them in those pathologic conditions in which they might be dangerous to health, or caution against unsafe dosages or methods or duration of administration or application, for the protection of the user. The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Real Lax Chewing Laxative—Pennsylvania Drug Products Corporation Pittsburgh Shipped between July 10 and Aug 7 1941 Composition a peppermint flavored gum containing phenolphthalein. Misbranded because label failed to warn adequately against use in those pathologic conditions wherein product might prove dangerous to health or against unsafe duration of administration for protection of user since label did not contain a warning against use when abdominal pain nausea vomiting or other symptoms of appendicitis are present and against frequent or continued use which might result in dependence on laxatives. —[D N J F D C 618 February 1943]

T S B Saline—T S Burns and Boys Company Buffalo Shipped March 18 1941 Composition essentially a mixture of partially dehydrated epsom salt and Glauber's salt with traces of magnesium carbonate and sodium chloride. Misbranded because indefinite dosage directions on label might cause danger to health of young children. Misbranded further because labeling did not adequately warn against giving it in those pathologic conditions wherein use of product might be dangerous to health or caution against unsafe dosage or duration of administration since the package carried no warning to avoid the product when symptoms of appendicitis are present such as abdominal pain nausea or vomiting or caution against frequent or continued use when it might result in dependence on cathartics to move the bowels. Again misbranded because of label misrepresentations that the product would be efficacious as a laxative and intestinal cleanser and effective in treating rheumatism constipation indigestion colds skin rash biliousness and many conditions due to faulty elimination since it would not be useful for such purposes. Misbranded further because of label representation that magnesium carbonate was an active ingredient whereas it was present only in traces. Misbranded also because label failed to bear common or usual name of each ingredient or an accurate statement of the quantity of contents. —[D N J F D C 556 November 1942]

Vitalax (Special Formula No 8558)—Medical Specialty Company San Antonio Texas (Repachager of product which originated in Bristol Tenn.) Shipped Feb 1 1941 Composition phenolphthalein (about 1 grain per tablet) with extracts of yeast and bile. Declared misbranded for the following reasons: labeling of tablets in original container bore no directions for use and in the case of the repackaged tablets the statement suggesting the dose was not a suitable direction for use of laxative tablets of this composition. Labeling failed to bear adequate warning against giving to children when such use might be dangerous to health or to caution against unsafe dosage or methods or duration of administration since adequate warning was not given against potential danger of establishing the laxative habit no warning to discontinue use if skin rash appeared and in the case of the repackaged portion there was no caution against use when symptoms of appendicitis are present. Label statements as to composition were false and misleading in not revealing the material fact that product contained phenolphthalein a coal tar laxative drug designations Vitalax and Vitamin B Laxative (repackaged portions) gave the false impression that the laxative action of the tablets was due to their vitamin or vitamin B content whereas it was actually due to the phenolphthalein. Label claims on repackaged portion as to stimulating liver function and producing abundant flow of bile for normal digestion and proper elimination without use of habit forming cathartic drugs were false and misleading since product was not efficacious for such purposes and did contain a habit forming cathartic drug namely phenolphthalein. Label claims (on repackaged portion in envelopes) as to toning digestive tract and stimulating flow of bile without use of habit forming cathartic drugs were false and misleading. Label claim non habit forming in one repackaged portion was false and misleading. Labeling failed to bear common or usual name of each active ingredient since it did not mention one of these phenolphthalein labels of repackaged portion did not list common or usual name of one active ingredient bile extract since this could not easily be identified under the terms used Sodium Taurocholate Sodium Glycocholate and Bile Salts Compound. —[D N J F D C 555 November 1942]

ERRORS IN ARTICLE ON DOCTOR SHORTAGE FROM OFFICE OF WAR INFORMATION

To the Editor—I have had a large number of calls recently in regard to temporary licensure for the practice of medicine in New York State from physicians who wish to come to New York State under such an arrangement. One of the applicants referred to in article he had read in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

I find in the September 25 issue on page 215 in the middle of the fifth paragraph of the article entitled "Doctor Shortage and Civilian Health in War Time" the following statement: "Only seven states have laws permitting temporary licensure. These are Delaware, Maine, Nevada, Pennsylvania, Washington, New York and Montana." I understand that this article is a comprehensive report prepared by the Office of War Information. I do not know to whom to direct this statement in regard to that information being incorrect.

So far as I am aware there has been no change in the New York law governing the practice of medicine permitting temporary licensure in the practice of medicine. I would be interested to know where the writer of this article obtained that information.

In the next paragraph, the sentence beginning on the last line in the first column reads as follows: "The service found that nine states had medical license reciprocity with New York but none of these states could, by law, admit the foreign doctors." This statement is in error, for at the present time there are no reciprocity agreements between New York State and any other state. The law governing endorsement of licenses was amended by act of legislature in 1940 and at that time all reciprocity agreements were abolished. I think if you will refer to your table entitled "Reciprocity and Endorsement Policies" as published in the statistical number since that time you will find that in that table there is no indication of reciprocity agreements between New York State and any other state. Under the present law a physician from any state who has met all the New York State requirements upon submitting proper credentials and paying the proper fees may receive an endorsement of that license. This is regardless of whether or not that state grants endorsement to a physician holding a New York medical license.

Secretary, New York State Board of Medical Examiners

IMMUNIZATION AGAINST INFECTIOUS DISEASES

To the Editor—The current comment on immunization against infectious diseases in large cities (THE JOURNAL, September 18) states that immunizations against typhoid were "negligible in frequency as compared with those against diphtheria and smallpox." It appears to be little known that in the spring of 1942 about 90 per cent of the population of the Territory of Hawaii received typhoid-paratyphoid inoculations. This program was instituted by the department surgeon (Brig Gen Edgar King) because there was no line of separation between military and civilian health problems in that territory. The wisdom of this move was dramatically revealed by the occurrence of an epidemic of typhoid in Honolulu (described in

the *Hawaiian Medical Journal*) shortly after the inoculation program was instituted (and long before it was completed). The incidence of typhoid in Hawaii during the postinoculation years should serve as the basis of an interesting study.

PREDICTION OF POLIOMYELITIS INCIDENCE IN EPIDEMIC YEARS

To the Editor—Attention was recently directed to the communication on the prediction of poliomyelitis incidence in epidemic years (THE JOURNAL, September 4, p 53). An effort was made to determine whether or not the experience in San Francisco coincided with that presented for Chicago.

As a result of a review of our recent epidemic years, apparently the observation can be made that the epidemiologic statistical pattern of infantile paralysis is still obscure, and the following conclusions may be reached:

1 The 1943 accelerated incidence in San Francisco should not be considered epidemic.

Poliomyelitis in San Francisco. Solid line, cases reported by week of onset. Dotted line, same using moving average (three weeks).

2 No standard for predicting the peak of an epidemic can be determined at least in San Francisco, as the interval from initial increase to peak varies between the years 1930 and 1934 from four to seven weeks.

3 Again, for San Francisco, it is not possible to assert with assurance that seasonal prevalence is fixed or to be predicted in any years. In 1930 the peak came in October, in 1934 in June, in the current cases the highest incidence was reported in August.

4 Geographically speaking, differences in incidence trends of this particular disease preclude the possibility of making statistical generalizations.

Attached is the chart from which these conclusions were drawn, depicting reported incidence by week of onset and showing the curve of incidence smoothed by use of moving averages for the three epidemic years 1930, 1934 and 1943.

"GROWTH ACCELERATING PROTEIN"

To the Editor —It is indeed surprising to me that your editorial staff (*THE JOURNAL*, May 22, p 232) would select the article by White and Sayers (*Proc Soc Exper Biol & Med* 51 270 [Nov] 1942) for special recognition. I call particular attention to that part of the article and the editorial which has to do with 'soybean protein,' because that is my special field. I want to make three particular criticisms of the original article.

1 The 'commercial soybean protein' used by the authors was obtained from the Medical Research Division, Sharp & Dohme, Inc. who in turn obtained the material from the Glidden Company. This product is one we make by a special process for an industrial adhesive. An alkaline treatment used in this process practically eliminates the possibility of this material being of good nutritional value. Our protein was further treated with alkali which would tend to decrease further the nutritive value. Although we had every reason to suspect a poor nutritional product we have fed this 'soybean protein' and have found our suspicions well founded. We can furnish more data than White and Sayers published that this product is poor nutritionally. This 'commercial soybean protein' is an adhesive used in the paper and fiberboard industry and is never sold or recommended for a food product.

2 White and Sayers state that they heated this material in an oven at 105 C for one hundred minutes to improve the nutritive values of the protein. They quote Wilgus, Norris and Heuser as their authority for this treatment. A check on this article will show that Wilgus, Norris and Heuser obtained the feeding materials for their studies from J W Hayward, then of the Wisconsin Experiment Station. By going to one of the papers from Wisconsin by Hayward, Steenbock and Bohstedt (*J Nutrition* 11 219 [March] 1936) we find on page 227 a table showing that heat in an electric oven had no appreciable effect on the nutritive value of soybean protein. It is apparent that White and Sayers not only used an inedible soybean product for their test but that the treatment they gave the product would not tend to increase its nutritive value.

3 The literature of science has many references to the high nutritive value of soy protein. We have data in the laboratory of the Glidden Company which will show the nutritive value of the protein as it is found in an edible product, soy flour, which is made for a food and not an adhesive, to be almost the same as the nutritive value of the protein of spray dried skimmed milk powder. The value of such a milk product is certainly accepted. In this laboratory we have data showing seven consecutive generations of rats raised on a simplified diet which derives its protein from soy flour. We discontinued the use of dehydrated yeast as a source of the vitamin B complex some years ago but for comparison with the data presented by White and Sayers we went back and hunted up data from our laboratory where we used yeast as the B complex source and 'Labco Vitamin Free' casein as the check lot of protein.

Protein level of diets 20 per cent

Test period fifty six days

Animals piebald rats 22 ± 1 day of age at start of trial

Source of Protein	Number of Animals	Average Daily Weight Gain in Grams	Average Daily Food Consumption
Casein	10	2.26	10.5
Soy flour	10	3.07	13.6

Inasmuch as methods for preparing isolated globulins of unquestionably high nutritive value have not been exhaustively explored, we feel that the utmost caution should be exercised in approving or condemning such newcomers in the field of protein nutrition.

USE OF THE TERM PARA

To the Editor —Although I do not wish to add further confusion to the question regarding the term para, I would like to state that I was taught that para is an abbreviation of and derived from the Latin gerundive form parturienda, the translation of which is 'is going to give birth.' It is for this reason that many obstetricians have applied the term para 1 and so on to a woman who is in labor for the first time and nullipara to one who has never borne a child. It seems to me that the change in the application of the term para has been made during recent years. It would be desirable if a general agreement could be reached in the application of this term for the sake of uniformity of all hospital records.

HANS STIDEMANN, Captain, M C, A U S

VITAMIN DEFICIENCY BY INTERFERENCE

To the Editor —In line with the article on "Vitamin Deficiency by Interference" in *THE JOURNAL*, September 18, page 151, it is interesting to note another evidence of this action. In attempts to prevent coccidiosis in chickens, it was shown (Holmes, C E, Deobold, H J, and Herrick, C A. *Sulfur and Rickets, Poultry Science* 17 136, 1938. *Diseases of Poultry*, edited by H E Biester and Louis Devries, Iowa State College Press, 1943, p 755) that, when 2 to 5 per cent of sulfur was included in a ration in which the sole source of vitamin D was cod liver oil, rickets developed. Apparently the sulfur made the vitamin D of the cod liver oil unavailable for absorption.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Accident Insurance Absence of Visible Contusion or Wound as Preventing Recovery for Death from Chloral and Bromide Poisoning—The defendant insurance company agreed to pay the beneficiary stated benefits if the insured died from bodily injuries effected directly and independently of all other causes through external violent and accidental means "of which there is a visible contusion or wound on the exterior of the body."

The insured died as a result of taking a medicinal compound containing cannabis chloral hydrate potassium bromide and extract of hyoscyamus. When the insurer refused to pay any benefits under the policy the beneficiary instituted suit and recovered judgment. On appeal the court of appeals of Tennessee, western section, reversed the judgment and ordered a new trial on the ground that while under the undisputed evidence the death of the insured resulted from a bodily injury effected by accidental means, it was not shown that the fatal injury was evidenced by a visible contusion or wound on the exterior of the body. *Travelers Ins Co v Ins't*, (Tenn) 121 S W (2d) 37 J A M A 113 2179 (Dec 9) 1939. On the second trial the sole issue was with respect to the existence of such evidence on the exterior of the body. At the conclusion of the beneficiary's case the trial judge directed a verdict for the defendant and the case was again appealed to the court of appeals of Tennessee, western section.

The insured was so constituted physically that a comparatively small amount of intoxicating liquor while not making him drunk, would result in his being rendered highly nervous after the effect had worn off. To relieve this condition, which occurred at irregular periods only, he was accustomed to taking the medicine described, which he procured at a drug store without a physician's prescription. On the evening of Nov 27, 1936 the insured had several drinks of gin and beer. He was not rendered noticeably intoxicated but nevertheless was so nervous the following day that he remained in bed. That night his wife, the beneficiary in this action, ordered some of the medicine over the telephone from a neighborhood drug store. A 2 ounce bottle of it was sent, with directions written on it to take "two teaspoonsful as needed." The insured was given a dose at 7 30 p m and another dose of 2 teaspoons about midnight. He apparently took some more of the medicine about 12 noon of the following day and another dose of 2 teaspoons about 3 o'clock. About 6 30 p m his wife noticed that he had a peculiar look about his eyes—that his eyes "looked kind of glassy"—and called in a friend of the family. Shortly after the arrival of this friend, the insured staggered back to his bed, fell face downward on it and went into a deep sleep. A physician was immediately summoned and found the insured in a condition of shock with "a pallor and a thready pulse." The insured was immediately taken in an ambulance to a hospital, where his stomach was washed and he was given cathartics and epinephrine. The driver of the ambulance testified that he observed "a little scraped place or a little scratched place" on insured's left leg and further observed that the insured's lips "were mighty blue—real dark blue, or purplish." The insured died while on the emergency table, death being attributed to chloral and bromide poisoning resulting from the cumulative effect of the medicine.

The sole question to be determined by the appellate court was whether there was any evidence before the trial court that there was a "wound or contusion" on the exterior of the insured's body evidencing the fatal injury. Admittedly, if there was no such evidence there was no liability on the part of the insured. A "wound," said the appellate court, is

An injury to the body of a person or animal, esp one caused by violence by which the continuity as skin, mucous membrane or conjunctiva is broken. Webster's New International Dictionary, second edition.

A "contusion" is

A bruise, an injury attended with more or less disorganization of the subcutaneous tissue and effusion of blood beneath the skin but without breaking the skin (ibid).

As justifying its conclusion that there was no wound or contusion in the present case, the court quoted at length from *Paist v Lina Ins Co*, 54 F (2d) 393, 60 F (2d) 476, in which the insured's death was caused by sunstroke and in which it was contended that since the insured's face was flushed and sunburned he had a "wound" or "contusion" within the meaning of the policy. The federal trial court in that case said

It might be just possible to bring it under the definition of wound given by the Century Dictionary as the meaning of the word in medical jurisprudence and cited by the plaintiff, but in insurance policies courts have been and are refused to adopt technical definitions and have adhered to the ordinary and popular meanings of words used. There is no reason why this rule should not work both ways. Certainly, in ordinary parlance "contusion" is almost exactly synonymous with "bruise," and to say that a flushed countenance is a wound would go beyond the limit of allowable interpretation.

On appeal the circuit court of appeals for the third circuit said with respect to the Paist case

We are here dealing with a written contract in which the parties agreed that the accident against which the insured was indemnified was one "evidenced by a visible contusion or wound on the exterior of the body." These words, "contusion," "wound," "visible on the exterior of the body" are of well known commonly understood meaning. "Contusion" which has its Latin origin "con" and "tundere," to strike, means a bruise or wound caused by a blow but where, as here, no physical blow is struck where there is no bruising, where the skin is not blown or bruised or blown broken certainly in common speech and common understanding the death of the plaintiff's husband from sunstroke cannot be said to be evidenced by visible contusion or wound on the exterior of the body.

Reverting to the facts of the case at bar, said the appellate court, apart from the scratch on the insured's leg, the condition relied on as constituting a wound or contusion was that just prior to his death his face was pale and his lips were somewhat swollen and blue. We do not think either condition was within the common, ordinary meaning of the words "wound or contusion." A pale face and swollen, blue lips might be regarded as indicating, and as a sign of, an internal disorder or even an injury, but we cannot conclude that either is of itself a wound or contusion within the ordinary meaning of those words, especially in the absence of any expert evidence on the point, which was the situation in this case.

There is, continued the court, moreover, another reason why the beneficiary cannot recover. The burden was on her to show a causal connection between the conditions relied on as constituting a wound or contusion and the fatal injury. In this respect she failed altogether. This is true not only with respect to the scratched place on the insured's leg but also with respect to the condition of his face and lips. As to the former, it is not contended that it had any connection with the injury that resulted in the insured's death. With respect to the blueness of the lips, the ambulance driver, who did not qualify as an expert and who was the only witness who undertook to testify about the matter, said that the condition was due to poor circulation. Apart from his testimony, if it can be regarded as having any probative value, the cause of the condition relied on by the beneficiary as meeting the policy requirement was left to speculation.

The judgment in favor of the insurance company was accordingly affirmed—*Ansley v Travelers Ins Co*, 173 S W (2d) 702 (Tenn, 1940).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1933 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Medullary Involvement in Tetanus A. B. Baker—p 709
Tuberculosis of Tonsils L. J. Rather—p 725

Pathology of Convalescent Poliovirus Infection in Man—Peers describes the pathologic aspect of the residual lesions of 3 patients with poliovirus who had survived 7, 15 and 18½ weeks from the onset of illness. Lesions in the cerebral cortex consisting of perivascular collars of lymphoid cells and interstitial foci of microglia and astrocytes are confined to the paracentral lobules. Only minimal lesions are found in the basal ganglia and thalamus. In the midbrain the substantia nigra presents the most severe damage. Lesions in the pons are confined to the tegmentum. Loss of nerve cells is extensive in Deiters' nuclei and more patchy and asymmetrical in the motor fifth and seventh nuclei. Single necrotic cells are still present four months after the acute illness. Perivascular infiltration diminishes and density of fibrous gliosis increases with the duration of convalescence. In the cerebellum, lesions are found only in the tectal nuclei and in the cortex of the vermis. The most prominent changes in the medulla consist of cell loss and scarring in the reticular substance similar to that found in the pons. The spinal cord presents an almost complete loss of nerve cells throughout the entire length of the anterior gray substance. In contrast the lateral horns are comparatively spared. Lesions in Clarke's column are patchy and asymmetrical and no definite changes appear in the posterior horns. Replacement gliosis in the anterior horns is at first abundant but delicate with bulky astrocytes. Later the cells shrink and the fibrils become coarser. In the white matter of the spinal cord there is a mild diffuse demyelination of most of the ventral and lateral columns with the exception of the pyramidal tracts. In the posterior columns partial demyelination is confined to the region of the comma tract of Schultze. The anterior nerve roots show severe degeneration consequent to the extensive loss of anterior horn cells. Almost all the coarse motor fibers have disappeared. In contrast, the fine myelinated efferent sympathetic fibers are mostly spared. In the ganglionic, dorsal root and sympathetic ganglia there are a very few small foci of

lymphoid cells. In the root ganglia only rare cells have disappeared, leaving behind capsules filled with mononuclear cells. The meninges contain only a few scanty foci of lymphoid cells, and no lesions were found in the choroid plexus.

Traumatic Rupture of Kidney—Adams reviews the problem of traumatic rupture of kidney on the basis of 7 cases seen by him in the course of the last two years. In 3 cases the trauma resulted from horse kicks, a frequent cause in rural areas. One patient fell from a merry-go-round, one fell from a golf bunker, a third suffered a flank injury due to a coasting accident, and the fourth was injured in a football game. The author stresses the need of early operation, but only after primary shock from trauma to nerve plexuses about the kidney pedicle is controlled and before secondary shock from hemorrhage occurs. Operations were performed on 6 of the 7 patients recently observed by him. Preoperative evidence of urinary extravasation usually is demonstrated satisfactorily by intravenous urography. Retrograde urography is thought to be unnecessary and undesirable except when additional information is essential. Urinary extravasation always indicates severe injury of the kidney and is a specific indication for operation. The presence or absence and the degree of hematuria are no criteria of the severity of renal damage because obviously hematuria is absent when the ureter has been severed or when the renal vessels have been ruptured and the kidney spared from injury or when the fracture line does not enter the renal pelvis. Should blood clots block the ureter, hematuria disappears.

Vascular Disease Following Toxemia of Pregnancy—According to Golden and his associates toxemia of pregnancy is an acute type of vascular disease occurring during the last half of pregnancy usually accompanied by greater or lesser degrees of water retention sometimes subsiding before delivery and always after delivery. It may appear in women with hitherto normal blood pressure as well as in those who are already hypertensive. The authors studied cases in which toxemia of pregnancy was imposed on a previously normal cardiovascular renal system. Toxemia of pregnancy (preeclampsia) a

and eclampsia) occurs in approximately 6 to 9 per cent of all pregnancies. From published reports it is apparent that roughly 25 per cent of women in whom toxemia develops are left with permanent postpartum vascular disease. In 2 per cent of all women who become pregnant permanent hypertension develops after pregnancy. The duration more than the severity of the toxemia determines the development of permanent postpartum vascular disease. A latent period of several months may intervene between toxemia of pregnancy and the development of recognizable permanent hypertension or albuminuria. After toxemia of pregnancy hypertension may persist for at least a year and then disappear. The postpartum course may be predominantly hypertensive or albuminuric apparently dependent on a similar predominance in pregnancy. The course is prone to be rapidly progressive in comparison with that of other types of hypertension. Death usually occurs as a result of uremia, cardiac failure or cerebral hemorrhage as in other types of hypertension. Renal changes such as a vascular sclerosis, hemorrhages and exudate occur but no instances of true albuminuric retinitis have been observed. Nephrosclerosis is the characteristic postmortem finding. The pathological condition of the kidneys in other respects is variable and at times may duplicate that of chronic glomerulonephritis. This is not surprising as both diseases start with a diffuse glomerular lesion and the hypertensive vascular disorders following the two diseases may run almost identical clinical courses. The late vascular effects of toxemia may be prevented by interrupting pregnancy before the hypertension and albuminuria have lasted for more than three weeks. This applies to mild and to severe toxemia.

Sulfadiazine Alone and with Antipneumococcus Serum in Pneumococcal Pneumonia—Shulman and Bullowa report their observations on 232 patients with pneumococcal pneumonia treated with sulfadiazine and 70 patients with this condition treated with rabbit antipneumococcus serum in addition. These patients admitted to the Pneumonia Service of Harlem Hospital from July 1, 1940 to June 30, 1941, were adults for whom the diagnosis of pneumonia was based on history and physical findings and confirmed by roentgen examination. Prior to the institution of therapy bacteriologic studies of the sputum and the blood were made. Of the 232 patients treated with sulfadiazine alone 31 died—a mortality of 13.4 per cent. Excluding those patients moribund on admission, who died within twenty-four hours, the mortality is 8.3 per cent. Nine of 29 patients or 31 per cent, with bacteremia died. The total mortality for the patients undergoing combination therapy was 14.3 per cent. The mortality for patients with bacteremia in this group was 22.2 per cent. The authors conclude that sulfadiazine is as effective as sulapyridine in the treatment of pneumococcal pneumonias. The mortality among patients who received both serum and sulfadiazine was slightly higher than that among the sulfadiazine treated patients but the former group was composed of more severely ill patients.

Acute Brucellosis—Three patients suffering from undulant fever afforded Wise an opportunity for study of the persistence of bacteremia and the behavior of demonstrable serum antibodies for *Brucella* throughout the course of the illness. All 3 patients came under observation during the first month of illness, and all received treatment with sulfonamide drugs. The clinically suspected diagnosis of undulant fever requires substantiation by isolation of *brucella* organisms from the patient's blood or demonstration of *brucella* agglutinins in high titer in the serum. Although the 3 patients had serum agglutinins in titers of 1:2,560 or higher, as well as *Brucella* suis in the blood at the time they came under observation, it was found that agglutinins may not be demonstrable for weeks after the onset of illness. Demonstrable complement fixing antibodies in the serum usually parallel agglutinins in time of appearance, but the complement fixation test has no real advantage over the more easily performed agglutination test. Determination of the opsonocytotoxic index has been found to be of no value for diagnosis. The 3 patients were febrile when they came under observation, and blood cultures positive for *Brucella* suis. Febrile episodes lasted usually seven to ten days, and in the intervals between febrile episodes the patients were symptom free despite the fact that bacteremia was demonstrated. It is not generally recognized that positive blood cultures may be obtained long after complete recovery from the acute illness

or even in the absence of a frank history of illness. Such possibilities should serve as a caution against interpretation of a single positive blood culture as indicating clinical disease. Sulfathiazole or sulfadiazine was given with little or no benefit. The use of these drugs has failed to prevent relapse. No significant changes in titers of *brucella* agglutinin or complement fixing antibodies were observed after sulfonamide therapy. A relatively prompt disappearance of serum agglutinins usually follows complete recovery, but complement fixing antibodies may persist for months.

- Hyperinsulinism and Hypoglycemia**—Holman, Wood and Stockton reviewed the literature of extrapancreatic islet adenomas and found 4 cases with symptoms of hyperinsulinism and hypoglycemia which were entirely controlled by removal of the extrapancreatic adenoma. To these 4 is added a fifth case in which the removal of one intrapancreatic adenoma failed to relieve the hypoglycemic symptoms but in which the removal of a second islet adenoma in the gastrosplenic ligament produced complete cure. The presence of multiple tumors is a relatively frequent occurrence in cases of hyperinsulinism in any operation undertaken in a case in which symptoms of hyperinsulinism are present, this possibility must be borne in mind. The entire pancreas must be exposed and searched for possible multiple intrapancreatic tumors. Failure to find an intrapancreatic tumor should be followed by careful search for an islet tumor in those sites where heterotopic pancreatic tissue is more frequently found, especially duodenum, stomach, jejunum, Meckel's diverticulum and ileum. Three other unusual cases are reported: one was that of a heterotopic islet adenoma of the duodenum and adrenal cortex without any hypoglycemic symptom, another of an islet carcinoma which presumably had been responsible for hypoglycemia of varying severity over a period of sixteen years. The third case presented severe episodes of hypoglycemia, and careful exploration was undertaken for an islet adenoma but none was found. In the course of the operation the pancreas was isolated from all surrounding structures although its arterial supply was not interrupted. No evidence of hypoglycemia have appeared after the operation. No explanation for this unexpected result is offered.

Hemorrhagic Hypotension and Its Treatment by Intra-Arterial and Intravenous Infusion of Blood—In experimental hemorrhagic shock in dogs, Kohlstaedt and Page tested the therapeutic effects of the intra-arterial infusion of blood, as compared to the intravenous route. The rationale is that the intra-arterial infusion would elevate blood pressure rapidly, thus restoring tissue perfusion without delay. When all the blood removed was returned by the intra-arterial route under a pressure of 50 mm of mercury the systemic arterial pressure rose rapidly and recovery occurred. The same amount of blood given intravenously usually caused recovery, but as the rise in blood pressure is slower some of the dogs died. Readministration of only 50 per cent of the blood by vein resulted in recovery in 30 per cent of the dogs, while the same amount given intra-arterially resulted in recovery of 75 per cent. Three patients in profound traumatic shock were treated by this method. The radial and the femoral artery were used. There was a rapid rise in the blood pressure in all instances. All the patients were treated surgically for their injuries. During the operations the blood pressure was maintained by intermittent intra-arterial infusion. After five or six hours of intra-arterial infusion the needle was removed and the artery ligated. One patient died of shock twenty-four hours later. The second patient died four days later from a cause not directly related to shock. The third patient recovered. For the cases in which the blood pressure is excessively low or when the amount of blood or plasma available is insufficient, the method deserves trial.

Rocky Mountain Spotted Fever—It has been accepted that the western strain of the virus of Rocky Mountain spotted fever is more virulent than the eastern strain and hence accompanied by a higher mortality rate. Observations have been made, according to Cameron, which indicate that this view is not entirely correct. Comparative studies on large numbers of cases from western and eastern states revealed that there was no significant difference in the fatality rate in comparative age groups. There is a significant difference between the fatality rates in the age group 40 and over and those of younger age groups. Immune rabbit serum given early following infection in an adequate dose gave the best results in repeated experiments on monkeys and guinea pigs. In studying the human cases it was impossible to use an untreated group as a control. The fatality rates were compared in a series of 19 cases treated with immune rabbit serum after the third day of the rash and in a series of 52 cases treated on or before the third day of

the rash. While the series are small, the inference is that immune serum is of value if used early in the infection. Up to the present there have been 13 cases reported in Delaware in 1943. There were three fatalities, in one of which immune rabbit serum had been given.

Duration of Gastric Cancer—Palmer calls attention to the extremes of growth of the gastric cancer. He quotes cases to demonstrate that the rate of development, growth and extension of the gastric cancer varies within wide limits some tumors being truly "acute" and others extremely "chronic." The factors determining or influencing these rates of growth remain to be ascertained. The clinical implications are numerous. The prognosis in certain gastric carcinomas is hopeless regardless of how "early" the diagnosis is made, in others the prognosis is good even though the diagnosis is late. The therapeutic implication is that, as a rule, all gastric carcinomas should be resected unless there exist proved distant metastases. It is possible that in certain cases the removal of the primary tumor may exert a favorable influence on the growth of the secondary lesions but at the present there is little evidence to support this view.

Local Use of Sulfonamides in Open Wounds—Overton implanted sulfonamides locally into 285 open wounds. He compares the results obtained in these cases with 215 open wounds treated earlier without implantation of sulfonamides. The following conclusions were made: 1 The local use of the sulfonamides has not improved the results in the treatment of open wounds when used as an adjunct to good surgery during the contaminated stage, however it was found not to delay in

healing time. 2 All of the sulfonamides produced some local tissue irritation as evidenced by the increase in serum and tendon adhesions. 3 The local use of the sulfonamides is not necessary in the early treatment of open wounds which can be thoroughly cleansed and debrided. These drugs may produce enough irritation to contraindicate their use in such cases. 4 The use of the sulfonamides may be of definite value when administered in badly disrupted wounds which cannot be thoroughly cleansed and debrided. When combined with the use of one of the drugs by mouth sulfonamides are invaluable in this type of case. 5 Early treatment of any open wound is thorough cleansing and the removal of all contaminated and nonviable material followed by wound support and rest. Under no circumstances should the sulfonamides be substituted for this treatment.

Absenteeism of Industrial Workers—Court presents charts on the basis of which he analyzes absenteeism among industrial workers. All of the increase in disability rates has been in respiratory diagnoses, the other major classifications having remained about stable. From 1939 through 1942, respiratory difficulties were both the most frequent and the only expanding major cause of disability. The almost universal use of supplementary vitamins and the wide availability of "cold shots" does not seem to have helped much. One of the charts shows for General Motors men the time lost in 1942 from short term sickness, serious sickness, nonoccupational accidents and occupational accidents. The relative unimportance of the last category is obvious. Recent public statements by poorly informed persons have exaggerated the importance of industrial accidents by 1000 per cent or more. Another chart compares the stable rate of serious sickness among General Motors factory workers, with a sharp increase in short term absenteeism which has occurred among these workers. An analysis of this rapidly increasing short term absenteeism shows that the workers themselves give personal sickness as the reason for nonattendance in about two thirds of all cases, with sickness of other members of the family and other personal needs making up the remainder. When this short term personal absence (alleged to be mostly sickness) is analyzed day by day it is found that it is heavily concentrated on Saturdays and Mondays. These days average about twice the lost time rate that is shown on payday each week. Thus it appears that the type of absenteeism which is currently most disturbing—that is short term absenteeism—is usually attributable to sickness which reaches epidemic proportions around the week end. Another striking fact about personal lost time is that absenteeism is concentrated among a few workers who compose a chronic fringe having more than their share of time off. One obvious characteristic is the relative youth of the group. A plant physician may be able in an important number of cases to help effect some reorientation of the individual's understanding of his job or his home problems which will enable him to cope better with those temptations which lead to excessive "week end sickness" and related types of absence.

Treatment of Carcinoma of Cervix at Charity Hospital—Garcia and Menville report observations on 226 patients with carcinoma of the cervix who were treated at Charity Hospital of Louisiana between April 1938 and August 1939. A combination of x-ray and radium therapy was employed whenever possible. Treatment usually began with external x-ray therapy, given in accordance with the technic worked out by Arneson and Quimby. The dose amounted to from 1,600 to 2,000 roentgens in air through each of six pelvic ports in a period of twenty-four days with 200 kilovolts 0.5 mm of copper plus 1 mm of aluminum filtration and 50 cm distance. In addition many of the patients had per vaginal x-ray therapy according to the method described by Cooper. The dosage through this route varied considerably but it seldom exceeded 5,000 roentgens. Radium therapy was administered approximately a month later by means of a modification of the technic of Regaud and Lacassagne. From 5,000 to 8,000 milligram hours was given in a period of four to eight days, about half in the cervical canal and half in the vaginal fornices. The absolute three year survival rate in primary cases is 37.7 per cent. Prognostic factors are evaluated and satisfactory agreement is shown between the results obtained and the figures reported from other clinics.

Urine Alcohol Test and the Drunken Driver—According to Behrer and Witzbach, alcohol is an important primary cause of traffic accidents. The alcohol concentration of the body is the best method for determining the causative factor for the nervous manifestations and incoordination present in the accused person. When the alcohol concentration of the urine is 0.07 per cent or less the subject is not greatly incapacitated when the concentration in the urine ranges from 0.07 per cent to 0.2 per cent a considerable number of people may be under the influence of alcohol, all persons having urinary alcohol concentrations above 0.2 per cent may be assumed to have been under the influence of alcohol. During 1942 the

Cincinnati Police Department submitted 224 urine samples which were examined for alcohol content, sugar, acetone and sedative type of drugs. Of this number 204 tests represented persons charged with driving while under the influence of alcohol the other 20 specimens were taken from dead pedestrians and suicides for evidence of intoxication. A study of the 20 fatalities showed 13 definitely intoxicated, 3 showed evidence of drinking and the remaining 4 were free of alcohol. Of the 204 persons arrested for drunken driving 7 were found to have insufficient alcohol to sustain the charge and dismissals were requested by the prosecution. Eleven of the drivers had alcohol concentrations from 0.07 to 0.19 per cent, 132 from 0.20 to 0.29 per cent, 42 from 0.30 to 0.39 per cent, 4 from 0.40 per cent upward. The authors cite facts which show that urine-alcohol tests do not penalize the moderate social drinker but do expose and aid in convicting the drunken driver who has consumed a large amount of alcohol.

Transmission of Spotted Fevers by Argasid Tick Ornithodoros Parkeri—Davis shows that the argasid tick Ornithodoros parkeri transmits the infectious agents of spotted fevers of the United States, Colombia and Brazil with equal facility. Transmission was effected by larvae, throughout the nymphal stages, and by the male and female. Females that fail in transmission may give rise to infective progeny. Transmission through the egg was observed in spotted fever of the United States to the F4 generation, in the spotted fever of Colombia to the F2 generation, and in the spotted fever of Brazil to the F1 generation. The invasiveness of the infecting agent was not lessened by continuous tick passage. Ticks that had fasted for one year produced typical infection, and progeny of these fasting ticks produced infections resulting in the death of the host. The data submitted suggest that this tick may be a factor in the maintenance of spotted fever in nature and, occasionally at least a vector to man.

Book Notices

Röntgenographic Technique: A Manual for Physicians, Students and Technicians. By Darron Artelle Rhinehart, A.M., M.D., F.A.C.R., Professor of Roentgenology and Applied Anatomy, School of Medicine, University of Arkansas Little Rock. Third edition. Cloth. Price \$5.00. Pp. 471 with 201 illustrations. Philadelphia: Lea & Febiger, 1947.

In the preface to this useful manual on x-ray technique it is stressed that the needs of x-ray technicians, medical students and physicians doing some roentgenographic work for themselves have been particularly kept in mind. Having thus clearly indicated the scope of the volume, the author proceeds to cover it quite adequately. In common with many textbooks of its kind, it appears to devote a little more space to physics than is necessary. The dark room layout illustrated on page 99 seems more cramped than it should be. In the sections dealing with x-ray examination of the extremities greater prominence should be given to the use of cardboard holders. The loss of fine detail and of adequate soft tissue rendition (inevitable when intensifying screens are used) can be partly avoided by the proper use of such film holders. Most of the illustrations in the text show the use of a cassette, and the accompanying roentgenographic reproductions show the high contrast inevitable with intensifying screens.

In connection with x-ray examination of the wrist, the author does not mention the value of posteroanterior or dorsoventral views made with the hand in slight ulnar deviation, in order to bring out detail in the scaphoid more clearly. For true lateral projections of the wrist merely rotating the hand is not sufficient, in this position only the radius and carpus are in lateral projection, the ulna is still in dorsoventral projection. For true lateral projections of the wrist it is usually necessary to turn the tube and use a horizontal beam.

In connection with x-ray examination of the hip, it would seem desirable to point out the advantages of lateral projection made with the leg flexed and abducted. Of course, this particular projection in the presence of a fractured femoral neck, can be made with safety only when the fragments have been immobilized by internal fixation. The illustration used for showing a lateral view of the femoral neck is not clear and deserves remaking. Similarly that showing the bladder, figure 191, appears to be fogged and should be remade.

In the section concerning examination of the gallbladder with tetraiodophenolphthalein, nausea is mentioned as a common complication. It might be worth pointing out in the next edition that this nausea can be completely eliminated by the simple expedient of having the patient hold his nose while drinking any of the popular preparations. There has recently been placed on the market a compressed tablet preparation which eliminates nausea almost if not entirely, irrespective of control of the olfactory apparatus.

The author mentions the use of fluoroscopy for preliminary determination of the presence or absence of opaque foreign bodies in the eye (page 439). We doubt if many roentgenologists would endorse this procedure. The dangers of fluoroscopy and indeed, of radiography deserve a little more stressing than is given in the present text. The dangers of radiography with portable apparatus have been vividly illustrated in recent months by the tragic incidents at certain large industrial plants, where many amputations of hands proved necessary following the indiscreet use of portable x-ray apparatus at too close a distance.

Most of the illustrations are clear and well reproduced. The type and format are also satisfactory. The book can be recommended for use by those for whom it was written.

A Handbook of Medical Library Practice Including Annotated Bibliographical Guides to the Literature and History of the Medical and Allied Sciences. Based on a Preliminary Manuscript by M. Irene Jones. Compiled by a Committee of the Medical Library Association. Edited by Janet Doe. Cloth. Price \$5. Pp. 609 with illustrations. Chicago: American Library Association, 1943.

This volume was compiled by a committee of the Medical Library Association under the leadership of Janet Doe of the Library of the New York Academy of Medicine. An original manuscript prepared by M. Irene Jones was the basis for the complete work. Data are here made available that are not easily found in many other places. There is, for example, a list of medical libraries possessing a hundred thousand or more

volumes in and out of America. There are chapters on periodical and book selection, ordering, cataloguing, subject headings, classification, pamphlets, pictures, maps and microfilms, a discussion of rare books and a guide to bibliographies, biographic collections and histories. The final chapter is a consideration of reference work by Eileen R. Cunningham. While the book will not have much of an appeal for the average physician, it is well nigh invaluable to any one concerned with libraries in the field of medicine. The statement relative to the *Quarterly Cumulative Index Medicus* deserves repetition for the attention of every physician.

This index is the most important current international index to medicine and the allied sciences. No medical library can afford to be without it. Its importance to the medical profession is acknowledged throughout the world. It is, of course, particularly useful to English speaking readers, but there is no other medical index of equal excellence and value published in any other country. It is conveniently arranged and is easy to consult rapidly.

The Conquest of Epidemic Disease: A Chapter in the History of Ideas. By Charles Edward Amory Winslow. Cloth. Price \$4.50. Pp. 411. Princeton, New Jersey: Princeton University Press, 1945.

The author is professor of public health in Yale University. His objective has been to write a history of the ideas on which have been based the efforts to control epidemic diseases. "How did the leaders of science really visualize a given problem in a given century, what was their solution and what were the reasons which dictated that solution?" The course of epidemicologic progress is described in detail.

A hurried summary can give only a general outline of the scope of the book. Following detailed reviews of supernatural medicine, demonic and divine, practices of which are not yet limited to the past or to remote places, account is given of the directing influence of observation and experience on medical thinking in Greece, in accord with the Greek concept of a universe of natural law. Hippocrates observed that each disease "has a nature of its own, and none arises without its natural cause," and in the case of epidemic diseases this cause is mainly disturbances of the body by atmospheric influences. Some five hundred years later Galen defined epidemic disease as one "which attacks all, or the greater number, arising from corruption of the air with the result that great numbers perish. Certain diseases, notably ophthalmia, skin diseases and phthisis were early recognized as contagious. The fact that epidemics always spared some persons was explained on the score of individual predisposition. These three factors—atmospheric influences, predisposition and contagion—dominated epidemiology until the nineteenth century. Winslow observes that while historians and poets suggested that epidemics were spread by contagion, miasmatic and constitutional factors received the main emphasis in medical writings. He points out that the Old Testament presented the first clean-cut conception of contagion and built on this conception a definite and well conceived program of differential diagnosis, isolation, quarantine and disinfection. For three hundred years after 1348 plagues raged in Europe and it was the Black Death which at last taught the communicability of disease by contact beyond all doubt. The numerous tracts put out to explain the causes and treatment of plague appear to be the first example of popular instruction in public health on a large scale and in these tracts contagion was accepted. It was in the sixteenth century that Fracastorius developed a remarkably complete and adequate theory of contagion in which the only major deviation from the modern conception was the lack of recognition of the biological nature of the contagious element. In the seventeenth century Athanasius Kircher presented the first clear concept of 'contagium animatum' and Leeuwenhoek the first to do so described and figured bacteria and protozoa. The stage was now fully set for a sound complete theory of contagion but the emphasis by Sydenham on the epidemic constitution of the atmosphere to the neglect of contagion in the spread of epidemics held back the progress of epidemiology for many years. The modern public health movement started in the first half of the nineteenth century with the great sanitary awakening led by Shadwick, Simon, Snow and Budd. The role of filth as the nurse of infectious disease, it not the mother and the nature and modes of spread of the contagions of cholera and typhoid were demonstrated even before their bacterial etiology was known. Finally led by Pasteur the germ theory of commun-

cable disease was established. Discovery of the carrier and of the insect host as well as the close analysis of modes of infection explained the occurrence of infectious disease when not traceable directly to contact as commonly understood. The book closes on a note of triumph for the germ theory and of reminder of unsolved problems. 'There is today a wholesome reaction against exclusive emphasis on the germs and a recognition of the importance—even in many germ diseases—of factors of constitutional resistance (diathesis) and of the influences of climate and season and nutrition upon vital resistance.'

The book is based on deep comprehensive study and able analysis of first hand information. As stated in the author's preface, the story has been told as far as possible in the actual words of the various participants and after a thorough analysis of their surviving works. There are also appropriate sketches of the participants. The long chapter on "The Impact of Yellow Fever" might well have included a brief comment on its solution. The role of vaccination in the control of small-pox might also have been considered even though the general subject of immunity is not included in the discussion. The book is a notable example of good historical writing and scholarship.

The Therapy of the Neuroses and Psychoses. A Socio-Psychobiologic Analysis and Resynthesis. By Samuel Henry Kravins, M.D., Associate in Psychiatry, University of Illinois College of Medicine, Chicago. Second edition. Cloth. Price, \$7.50. Pp. 767 with 6 illustrations. Philadelphia: Lea & Febiger, 1943.

This is a good book on psychiatric treatment. Both psychologic and medical therapeutic measures are discussed in some detail. In spite of the title there is a considerable portion on psychosomatic diseases, which are perhaps not really neuroses in a technical sense. The explanations which are given are up to date and carefully presented, and the style is good. All of the mental disorders which would interest any one doing therapy with mental cases are well covered. While some variations of medical treatment are not discussed, the presentation as a whole is quite detailed and adequate. There is nothing dramatically new, but this volume is one of the few books that contain such specific material on treatment of mental cases a subject which is becoming more and more important today with the return of mentally and nervously disordered members of the armed forces. There is some discussion of the war required mental disorders and there is less discussion of the psychoanalytic method in this than in the previous edition, however, much of the discussion is predicated on psychoanalytic concepts, although not expressed in psychoanalytic terms. There are a number of case histories which are well presented and in most instances form quite conclusive evidence of the therapeutic methods which the author describes. The psychiatrist and the general practitioner who have to treat neuroses and psychoses and psychosomatic complaints should be able to get much valuable information.

Notes on Gas Gangrene: Prevention, Diagnosis, Treatment with an Account of the Technique of Wound Excision and a Scheme for the Bacteriological Investigation of War Wounds. By the War Wounds Committee of the Medical Research Council and the Committee of London Sector Pathologists. Medical Research Council War Memorandum No. 2. Second edition. Paper. Price, 6d. Pp. 28. London: His Majesty's Stationery Office, 1943.

This paper gives a thorough and complete discussion of all the medical, surgical and pathologic aspects of gas gangrene. It represents a balanced view of British experience in the subject, therapeutic as well as diagnostic. It is a sober, well balanced dissertation. In concise form and in simple language there are presented in order the clinical aspects of the disease, its prophylaxis and the laboratory methods of diagnosis. The bacteriologic portions are particularly good. Much ink has been spilled in the complexities of the etiologic anaerobes. That error is not made here. On the contrary, the laboratory procedures given have the double virtue of being short and accurate.

The Nature, Method & Purpose of Diagnosis. By Henry Cohen, M.D., F.R.C.P., F.R.C., Professor of Medicine, University of Liverpool. The Skinner Lecture. Paper. Price, 1s. Pp. 27. Cambridge University Press, 1943.

This booklet contains Dr. Cohen's Otis Skinner Lecture delivered under the auspices of the Faculty of Radiologists at the Royal Society of Medicine. As the title implies, this is a philosophic discussion of the larger aspects of diagnosis.

Vertebrate Photoreceptors. By Samuel R. Detweiler, Professor of Anatomy, College of Physicians and Surgeons, Columbia University, New York. Cloth. Price, \$1.15. Pp. 181 with 110 illustrations. New York: Macmillan Company, 1943.

Pegunung with a short description of the eye as a whole in various vertebrates, the author goes on to a more detailed study of the vertebrate retina. With a careful digest of the literature is included a summary of his own studies, including measurement of the retina in twenty-seven different vertebrates with illustrations from his own photomicrographs. Various forms of the macular area are illustrated and adequate consideration is given to Polyak's work which has necessitated a modification of our simple conception of the conduction pathways in the retina to a much more complex one. The minute histology of the rods and cones and their development are reviewed. The author estimates that there are about seven million cones in the human retina and from seventy-five to one hundred and seventy million rods. His review and personal studies have convinced him that the duplicity theory is valid, i.e., that the cones and rods form distinct systems mediating vision in high and low degrees of illumination respectively.

Consideration of the habits of various vertebrates is, generally speaking, in accord with what one would expect from this theory, cones predominating in the retinas of diurnal animals while in nocturnal forms rods are chiefly or exclusively present. Some apparent exceptions are the presence of abundant rods in the strictly diurnal chicken and of cones, though small ones, in the owl. Wall's conclusions that cones may change to rods during evolution, involving a change of habits in certain vertebrates, is discussed.

The latter part of the book, dealing with the functions of the retina in relation to its anatomic structure, is of especial interest. The author has critically analyzed the evidence for various theories and, on the whole, is inclined to emphasize the need for further experimental evidence as regards most of them. Although migration of pigment during light adaptation has been conclusively demonstrated in many forms by various observers, including the author, it is absent in other forms and has not been conclusively shown to occur in any of the mammals in spite of statements to the contrary, which persist in many textbooks. The same is true of contraction of the cones and elongation of the rods during light adaptation, which has not been proved to occur in mammals although it is definite in many lower forms.

In at least some forms showing these photomechanical responses, they disappear following section of the optic nerve and also, according to Arey, have a definite relation to eye movements. A peculiar phenomenon of diurnal rhythm in these reactions observed by Welch and Osborn has been confirmed by Arey and Mundt. The changes of extreme dark adaptation were found only in animals whose eyes were removed at night, regardless of how long the animals had been dark adapted. It is concluded that, while these photomechanical responses are of value for dark adaptation in those forms in which they occur, they cannot be regarded as explaining the phenomenon.

While we are accustomed to consider our own visual apparatus as at the top of the scale from a functional and evolutionary standpoint, there is evidence from comparative anatomy that this is by no means the case. In birds the cones are much more closely packed in the foveal area than in man, there being about one million cones per square millimeter in Buteo as compared with a hundred and sixty thousand in man. In the goldfinch the internal nuclear layer is five times as thick as the vitreous, whereas in man the internal is actually narrower than the external nuclear layer, another indication of much greater visual acuity in the bird. The occurrence of well developed foveas in many lower forms, such as the lizards and in forms in which complete decussation of the optic nerve fibers occurs, deprives of all validity Elliott Smith's assumption that the fovea is a criterion of place in the evolutionary scale.

The facts concerning biochemical changes in the retina during adaptation are reviewed and a final chapter is devoted to the effects of vitamin A deficiency. In addition to the well known functional findings as revealed by adaptation tests the author describes certain degenerative changes, as shown by

microscopic studies, which occur in the rods after prolonged vitamin A deficiency. These, as shown by the author's associate Johnson, may reach extreme degrees and, although recovery from such changes was shown to occur, it was slow, requiring ten to eighteen weeks in rats and was not complete at the end of this time.

A Text Book of Pathology. An Introduction to Medicine. By William Boyd M.D. F.R.C.P. Professor of Pathology and Bacteriology in the University of Toronto. Toronto. Fourth edition. Cloth. Price \$10. Pp. 1008 with 519 illustrations. Philadelphia: Lea & Febiger 1943.

The first edition appeared in 1932. The publication of four editions in eleven years is an indication of its popularity as a textbook among medical students, for whom it was primarily written, and of the rapid changes that are taking place in pathology. The modern point of view in pathology, still not recognized by many physicians, considers disease from its physiologic aspect against the background of morbid anatomy and histology. The structural changes induced by disease are still the chief concern of the pathologist but with the added factor of the effects of these changes on the function of the diseased organ. This is definitely the point of view from which Boyd's book is written. This edition is characterized by the same clear style, the same readability and the same apt allusion and deft turn of phrase that have been such prominent features of previous editions. It is fifty-six pages shorter than the third edition and is illustrated with 490 'engravings' and 29 colored plates. Three hundred and forty-six pages are devoted to general pathology, 631 to special pathology and 37 to the index.

This revision may lay claim to be a thorough one because in addition to new material, much has been rewritten, much has been condensed through a tightening of the belt of speech and a considerable amount has been deleted. The principal deletions are the chapter on body constants in disease, the sections on immunity and hypersensitiveness and on the principles of heredity and much bacteriologic detail in the chapter on bacterial infections. All these subjects are dealt with more adequately in textbooks in other fields and should have been learned by medical students in other courses that are prerequisite to the study of pathology.

In the preface, twenty-eight additions are listed. Among the more important of these are vitamin K in relation to thrombosis, histoplasmosis, liposarcoma, necrosis of the liver in burns, spread of tumors by the vertebral system of veins, virus pneumonia and radiation pneumonitis, cystic fibrosis of the pancreas, the renal juxtaglomerular apparatus, the relation of the kidney to hypertension, crush nephritis, Hunner's ulcer, blood phosphatase in carcinoma of the prostate, fibrosing adenomatosis of the breast, Boeck's sarcoid, the Rh factor in erythroblastosis fetalis and lesions of the intervertebral disks. Seventeen sections 'have been largely or in part rewritten,' such as the etiology of tumors, cirrhosis of the liver, goiter, pathologic physiology of the spleen, etiologic agents in carcinoma of the breast, the etiology of atheroma, of cholecystitis and of diabetes, the pathogenesis of lobar pneumonia, endometriosis, and the etiology of poliomyelitis.

The qualities of this book justify its popularity among medical students. While definitely not written for either practicing physicians or pathologists, both these groups will find in it much that is interesting and valuable. On the whole, the opinions expressed, often quite dogmatically, by the author are sound and in harmony with the established facts of modern pathology.

Annual Review of Physiology. Volume V. Edited by James Murray Luck, Stanford University. Associate Editor Victor E. Hall, Stanford University. Cloth. Price \$5. Pp. 613. Stanford University P. O. Annual Reviews Inc. 1943.

It is recognized in the preface to this volume that probably all reviews which will appear for the duration of the war will have to omit reference to important foreign scientific publications. Nevertheless the table of contents offers an impressive array of physiologic subjects reviewed by an equally-competent group of authorities. The reviews of this series including the one under consideration, are quite invaluable for research workers and medical libraries. They should be also of great assistance to scientifically minded workers everywhere who attempt to keep abreast of the rapid advance of science.

Clinical Roentgenology of the Cardiovascular System. By Hugo Roessler M.D. F.A.C.P. Associate Professor of Roentgenology and Cardiologist, Department of Medicine, Temple University School of Medicine, Philadelphia. Second edition. Cloth. Price \$7.50. Pp. 480 with 337 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas 1941.

The author has considerably enlarged and revamped the text in this edition to bring the material up to date. The illustrations have been expanded and improve the presentation by including more graphic case reports. The author's experience in this field together with his background of teaching research and clinical practice makes him well qualified to deal adequately with the subject. The book is useful for the beginner, but he will have to absorb it piecemeal. It is excellently suited for the cardiologist, since it integrates roentgenology with clinical states. It is well adapted for the roentgenologist since it gives him a clinical and anatomic background of the conditions considered making his point of view more complete and suitable as a consultant. It will be found useful as a reference book. It is therefore regrettable that at times the style makes it difficult to follow the author's thoughts, that certain words are used in an unusual sense, that more headings of subdivisions have not been introduced and that the illustrations have not been placed at the end of each section rather than interspersed in the text. Further it would have helped if the author had set off a section in the legend of every illustration devoted to comment in which he could integrate the points for which the case report was presented; this is done in only a few cases. This lack at times makes it difficult to find out what the figure is supposed to illustrate. The reproductions are excellent, and the illustrative material is arranged so that it can be used independently of the text. Only one error was noted in the illustrations, namely that the chest lead record of the second electrocardiogram in figure 281 is reversed. Considering the merits of this excellent book these are relatively minor criticisms. The author is to be commended for his courage in omitting references in the text to particular communications in order to avoid the pitfall, found in many textbooks, of giving credit to particular authors rather than in pointing out the broad sweep of subject development. Polemics are avoided, and the deductions presented are those of the author himself. The bibliography is extensive and should meet the requirements for further study of any reader. It seems, therefore, that this book admirably fulfils a real need in clinical practice.

Pictorial Handbook of Fracture Treatment. [By] Edward L. Compere M.D. F.A.C.S. Associate Professor of Surgery, Northwestern University Medical School, Chicago and Sam W. Banks M.D. Associate in Surgery, Northwestern University Medical School. Cloth. Price \$4.25. Pp. 351 with 171 illustrations. Chicago: Year Book Publishers Inc. 1943.

This handbook was compiled particularly for the general practitioner and medical students. The authors have presented the simplest principles and methods which they have found satisfactory for the treatment of fractures. The excellent illustrations by Dr. Harold Laufman give a graphic presentation of the technic described in the text and make the subject matter more readily comprehensible. The authors follow the methods of treatment of fractures and dislocations described in the modern textbooks of Boehler, Campbell, Key, Conwell, Magnuson, Scudder, Speed and Watson-Jones. The subject matter is condensed and is written to substitute for the larger textbooks. The general considerations of treatment of fractures are limited to the essential facts. Then fractures are taken up according to the parts involved and the authors' method of choice is described. In some of the difficult fractures the method of necessity involves technical difficulties which it would be hard to expect the student and general practitioner to carry out, such as the five pin treatment for the fracture of the neck of the femur as well as the various techniques of reconstruction when this fracture becomes ununited. Bone grafts are described with clearness but this does not make them any simpler or safer to do in the hands of the inexperienced. On the whole the book is well written and the illustrations add a great deal for the simplification and clarity of this large subject. The book is concise and a good condensation of the larger textbooks on fractures.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES, NOR SPECIFICALLY STATED IN THE REPLY. ADVISORY CORRECTIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. LETTERS MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ACUTE FEBRILE ILLNESS AND ADMINISTRATION OF SULFONAMIDES

To the Editor—I have had several interesting cases at a camp in the Catskills during this past summer and hope that you can help me explain them. These were all of a similar nature. They were all characterized by an acute onset with headache and no other physical findings except temperature from 101 to 103 F. Two of the patients not treated with sulfadiazine developed signs in the chest, which were not of a classic pneumonia and an increasing cough. One of these reached a temperature of 104 F on the fifth day and responded rapidly to sulfadiazine. The other patients (4) were treated immediately at onset with sulfadiazine and were better by the next day. These patients were all children from 9 to 12 years of age. The total amount of sulfadiazine varied from 50 to 90 grains (3.25 to 6 Gm). Headache started to disappear almost immediately on administration of sulfadiazine without any other drug. I have spoken to another physician in this locality who has had similar cases but he states that he has had some rapid cures without sulfadiazine. I would appreciate any information you can give me.

M. D., New York

ANSWER—Although it may be that the epidemic disease referred to was an unusual one in which the sulfonamides were helpful, the few details given strongly suggest that it was one of the syndromes called "primary atypical pneumonia, etiology unknown" or virus pneumonia. It appears that in the epidemic form of this grippike or influenza-like syndrome the majority of cases are mild and without pneumonia, which casts doubt on the wisdom of using the word "pneumonia" to name it. Some more general name like the ones just mentioned would seem preferable. An example of a similar epidemic in a summer camp is described by Iverson (*Bull. Johns Hopkins Hosp.* 72:89 [Feb.] 1943), in which pneumonia occurred in certain cases. The sulfonamide compounds are not of value in infections of this sort. Although it may be too late now, it would have been of interest to determine the presence or absence of cold agglutinins in the blood of these patients (*THE JOURNAL*, June 5, 1943, p. 369).

It is doubtful that pneumonia developed in the 2 cases mentioned because sulfadiazine was not given, and equally doubtful that sulfadiazine alone caused the immediate rapid response noted.

NITRATES IN VEGETABLES NOT TOXIC FOR MAN

To the Editor—There is an idea prevalent among the people around here that nitrate of soda used as a fertilizer to vegetable crops is injurious to human beings. People will get sick after eating certain vegetables and then say "I should have known better than to eat those cabbages or watermelons that have been grown with nitrate of soda." Since nitrogen is essential to plant growth I am unable to see why the application of nitrate of soda to hasten growth could be injurious to the human organism. Is there any evidence that the use of nitrate of soda as a commercial fertilizer to certain fruits and vegetables is in any way injurious to the person eating it?

J. Street Brewer, M.D., Roseboro, N. C.

ANSWER—Nitrogen is one of the most important plant nutrients and is usually the limiting factor in the growth of practically all crops. The general opinion is that it may be possible under extremely unusual conditions for nitrate to accumulate in the vegetative portion of the plant. This has been recorded for tobacco which has had a surplus of nitrate of soda applied to it. The veterinarians state that there is one case on record of a toxic reaction of stock to a field which had an extremely heavy application of nitrate of soda. In general nitrate which is applied as fertilizer is rapidly converted to other forms of nitrogen if not immediately used by the plant. The plant serves as a reducing system and converts the assimilated nitrate to nitrite, to ammonia, to amino acids and to protein constituents. Tollingham in *Plant Biochemistry*, discussing nitrogenous compositions of tomato plants, states that "these data show almost complete disappearance of nitrate in passing from the roots to the tip of the stem but there is a serious reappearance of this fraction in the conducting system of the leaf. This may signify, of course, translocation toward the leaf more rapidly than will allow reduction by the stem mechanism, but it is apparent that the leaf lamina promptly disposes of nitrate." Nightingale (*New Jersey Agricultural Experiment Station Bulletin* 461, 1928) found 10 to 13 per cent

of the total nitrogen present as nitrate in all parts of growing tomato plants except the leaf blade. Bridges and Mattice indicate that a watermelon contains 0.4 per cent of protein (probably N times 6.25) or 0.064 per cent nitrogen, if 15 per cent of this is nitrate nitrogen, equaling 0.0096 per cent N as nitrate or 0.042 per cent nitrate as NO_3 . It would hence require 2,500 Gm (over 5 pounds) of watermelon to contain 1 Gm of nitrate. If one ate this much one would be sick from something besides nitrate poisoning. Furthermore, Merck's Index gives the clinical dose from 0.2 to 1.3 Gm of potassium nitrate. Toxic amounts are much greater. If nitrate poisoning does occur, one would expect it from market gardening centers where heavy fertilization is the rule. Record of such an occurrence has not been found.

There is no evidence to support the belief that the use of nitrate of soda in the growing of fruit and vegetables is in any way injurious to people who eat such produce.

REPEATED BLOOD DONATIONS AND IMMUNE ANTIBODIES

To the Editor—Is there any scientific evidence to warrant the assumption that immune bodies, specific or general, might be reduced appreciably by repeated donations of blood so that the donor's resistance to infection would be materially affected?

R. V. Brokaw, M.D., Champaign, Ill.

ANSWER—There is no evidence that the periodic donation of blood as practiced by professional donors or persons donating their blood repeatedly to the Red Cross reduces appreciably the capacity of the body to form immune antibodies. If these small donations have any effect at all, it would more likely be a stimulating one. According to the present view antibodies are modified globulins, and to reduce the capacity of the body to produce antibodies rather drastic measures are necessary, sufficient to bring about a hypoproteinemia. This has been accomplished in experimental animals, for example, by feeding young rabbits a low protein diet and in adult rabbits by supplementing a low protein diet by plasmapheresis (Cannon, P. R., Chase, W. E. and Wissler, R. W. *J. Immunol.* 47:133 [Aug.] 1943).

INFRAORBITAL EDEMA AND EXOPHTHALMOS AFTER THYROIDECTOMY

To the Editor—The exophthalmos associated with hyperthyroidism not infrequently is increased following removal of the goiter. In a few patients the exophthalmos is complicated by infraorbital edema. What is the physiologic basis of that type of edema and what is the favored treatment? The cases cited average a metabolic rate of between plus 5 and plus 10.

Robert Hoffman, M.D., South Bend, Ind.

ANSWER—The cause of infraorbital edema and increase in exophthalmos following subtotal thyroidectomy is not clearly understood.

The most logical explanation so far presented is that it appears to be related to disturbances in pituitary function. The most interesting aspect of the problem is that the exophthalmos often increases when the basal metabolism is within normal limits. However, there is too much tendency to create the impression that this phenomenon occurs more frequently than it does.

Some improvement seems to have followed the combined administration of strong solution of iodine and desiccated thyroid. This is probably the most satisfactory treatment at the present time.

Irradiation of the pituitary has been tried with questionable results.

It is rarely necessary to resort to any operative procedure such as removal of the roof of the orbit to allow the eyeball to sink back into the skull.

ADHERENT SCAR IN FRONT OF TRACHEA

To the Editor—On page 68 in the Sept. 4, 1943 issue of *The Journal under Queries and Minor Notes* there is an item about an adherent scar in front of the trachea following a thyroidectomy. The question is asked about a deep funnel shaped scar which is adherent to the trachea. Might not this be due to the so-called prethyroid muscles being widely separated in this area and leaving nothing but scar tissue between the skin surface and the trachea? When the scar is excised it would seem desirable to pull the deep prethyroid muscles, the sternothyroid muscles together in the midline with interrupted sutures and do the same for the superficial prethyroid muscle, the sternothyroid muscle, and thereby eliminate the depression in this area over the trachea. This is an important step in any thyroidectomy in my estimation, and certainly it is true in women because this preserves the contour of the neck rather than having a depression over the trachea when the muscles are not sutured together in the midline.

SULFONAMIDES IN BRONCHIAL SECRETION

THE EFFECT OF SULFONAMIDES IN
BRONCHIECTASIS

CHARLES M. NORRIS, M.D.
PHILADELPHIA

The frequency of chronic infectious diseases of the bronchi and the limitations of the various medical measures used in their treatment would appear to justify an investigation of the possibilities of sulfonamide therapy, yet a review of the recent literature shows only a few brief references to this subject. Although the pathologic changes in many of these diseases are at least partially irreversible, it would seem logical that diminution in the infective factor should result in improvement. Acquired bronchiectasis and chronic asthmatic bronchitis are characterized in their earlier phases by impairment in the function of the bronchi and bronchioles, gross structural disease is in most cases a secondary development. The possibility of restoring normal structure and function by medical measures is not a likely one, but partial elimination of infection would be expected to have a favorable effect on the symptoms and on the natural course of the disease.

The distribution of the sulfonamides, including sulfadiazine,¹ among the various body fluids has been thoroughly studied. The purpose of the first part of our investigation was to determine (1) the correlation between blood levels of sulfonamide following oral administration and their concentration in bronchial secretion and (2) the concentration in bronchial secretion resulting from the intratracheal or intrabronchial instillation of sulfonamide at twenty-four hour intervals following the instillation.

Because the character of bronchial secretion presents a special problem in chemical analysis, a modification of the Bratton and Marshall method for the quantitative determination of sulfonamide concentration, applicable to bronchial secretion, was devised. Because of the obvious inaccuracies which would result from the use of sputum for such analyses, only bronchoscopic specimens were submitted to examination. The use of cocaine hydrochloride as a local anesthetic preliminary to bronchoscopy does not interfere with the color

reaction on which the determination is based. Atropine was omitted from the usual prebronchoscopic hypodermic because of its drying effect on the bronchial secretion.

DETERMINATION OF SULFONAMIDE IN BRONCHIAL SECRETION, A METHOD FOR OBTAINING A CLEAR FILTRATE²

Solutions used, except 10 per cent sodium hydroxide, are those of Bratton and Marshall. Transfer secretion to beaker, obtaining weight by difference. Add gradually 10 per cent sodium hydroxide enough to render the secretion homogeneous (not more than an equal volume). Rinse solution into a stoppered graduate with saponin solution, diluting until viscosity appears low. Add 15 per cent trichloroacetic acid solution, a small amount at a time with gentle shaking, until the point is reached at which a little of the precipitate remains undissolved after prolonged shaking. Note volume. Divide latter by weight of sample of secretion to obtain dilution. Remove to a small flask the number of cubic centimeters corresponding to 1 Gm. of secretion and add enough saponin solution to bring the volume to 16 cc. Add 4 cc. of 15 per cent trichloroacetic acid solution, shake well, filter and proceed with the clear filtrate as with a blood filtrate.

RELATION BETWEEN CONCENTRATIONS OF SULFON- AMIDE IN BRONCHIAL SECRETION AND IN BLOOD AFTER ORAL ADMINISTRATION

The amount of secretion present in the bronchial tree of normal subjects is insufficient to permit collection of adequate amounts for chemical analysis. Therefore, as subjects for this investigation, 12 patients with acquired bronchiectasis under treatment at the Chevalier Jackson Bronchoscopic Clinic were chosen, an effort being made to select those with varying degrees of disease and to include patients who produced but small amounts of sputum as well as those with much expectoration. The bronchiectasis was of the saccular type in 8 cases and of the cylindric or fusiform type in 4.

Sulfadiazine was given by mouth in sufficient dosage to maintain adequate blood levels. Specimens of bronchial secretion were obtained by bronchoscopy at intervals of from one to four days and the concentration of sulfadiazine determined by the method described. The results were then compared with the concentrations in specimens of blood taken at the time of bronchoscopy.

Results—The results of the individual determinations are shown in table 1. The concentrations of sulfadiazine in bronchial secretion range from 18 to 116 mg. per hundred grams, with corresponding blood sulfadiazine levels of from 39 mg. to 164 mg. per hundred cubic centimeters.

From the Chevalier Jackson Bronchoscopic Clinic, Temple University Hospital.

³ The author is indebted to Robert H. Hamilton, Ph.D., M.D., associate professor of physiological chemistry, Temple University School of Medicine, for this modification which he developed and for the designation of technique.

The average ratio between the two concentrations (bronchial blood) was 0.58, with an average variation from the mean of 0.08 or 14.0 per cent. The ratio obtained in considering only those determinations with the higher results (blood levels from 10.0 to 16.4 mg per hundred cubic centimeters) is only slightly higher (0.61) than that obtained by considering only the determinations with the lower results (0.55). The values obtained in those patients who produced but little bronchial secretion differed to no significant degree from those in the patients who produced large amounts, furthermore the ratios obtained in the cases of saccular bronchiectasis do not differ appreciably from those

SULFONAMIDE CONCENTRATION IN BRONCHIAL SECRETION FOLLOWING INTRATRACHEAL OR INTRABRONCHIAL INSTILLATION

The feasibility of using solutions showing bactericidal or bacteriostatic activity for intrabronchial instillation or lavage has been demonstrated by Kolmer,⁴ Stitt⁵ Moore⁶ and others. As subjects for this investigation 10 patients having acquired bronchiectasis were used. In all, eighteen instillations were performed, a 5 per cent suspension of microcrystalline sulfathiazole⁷ being

used in 12 instances and a 2.5 per cent aqueous solution of sulfadiazine⁸ in 6. Several of the instillations were performed bronchoscopically, the remainder were performed by instillation through the larynx following preliminary cocaine anesthesia. Specimens of bronchial

secretion were obtained by bronchoscopic aspiration at twenty-four hour intervals and the concentration of sulfonamide determined by the aforementioned method.

Results.—The results are given in table 2. The values obtained following instillation of microcrystalline sulfathiazole suspension appeared to depend largely on the amount of sputum being produced at the time of the instillation. The 2 cases in which unusually large concentrations were found at the end of twenty-four hours were those in which the average daily sputum volume had been 10 cc or less, much smaller concentrations were found in the remaining cases. In 2

7 Microcrystalline sulfathiazole 5.0 Gm., strong solution of iodine (Tugols solution) 2.0 cc., distilled water to 100.0 cc.

8 Sulfadiazine powder 2.5 Gm., triethanolamine 7.5 cc., butyl para hydroxybenzoate 0.05 Gm., boiled distilled water to 100.0 cc.

of the amount of sputum being produced at the time of instillation. Presumably this is because the sulfadiazine, being in aqueous solution, is more rapidly eliminated by absorption and expectoration than the suspension of microcrystalline sulfathiazole.

EFFECT OF SULFADIAZINE GIVEN ORALLY IN ACQUIRED BRONCHITIS

The 10 patients used as subjects for this investigation were given sulfadiazine by mouth in courses lasting from four to fifteen days. As an adjuvant measure to improve bronchial drainage, bronchoscopic aspiration was performed at intervals of from two to four days during the time the sulfadiazine was being administered. Bronchoscopic specimens were obtained for bacteriologic study at the beginning and end of each course.

several reasons.⁹ In the first place, spontaneous alterations in bronchectatic flora are presumably rather frequent, so that the disappearance of an organism from the culture during the period of treatment does not necessarily mean that it has been eliminated by the specific therapy. Careful examination of table 4 will show several instances in which organisms not present before treatment were recovered in the bronchial secretion after treatment, in most cases these organisms were of the group ordinarily considered to constitute the normal throat flora, and their appearance in and disappearance from the bronchial cultures is therefore probably of no great significance.

The relative pathogenicity of the various organisms present in a given case is difficult to estimate except in a general way. Ordinarily, hemolytic streptococci

TABLE 4—Effect of Sulfadiazine Given Orally (Combined with Bronchoscopic Aspiration) in Ten Cases of Bronchectasis

and daily sputum volumes were recorded accurately. An attempt was made to maintain blood levels between 8 and 12 mg per hundred cubic centimeters and blood counts and urinalyses were obtained at suitable intervals.

An estimation of the clinical effect was based on (1) reduction in amount of expectoration, and (2) alteration in the bacterial flora of the bronchial secretion as determined in specimens removed bronchoscopically.

Results.—The results are presented in table 4. The outstanding effect was a definite and rather pronounced decrease in the daily sputum volume. The actual reductions in volume varied from 55 to 81 per cent with an average of 69 per cent, so that most of the patients at the end of the combined course of sulfadiazine therapy and bronchoscopic aspiration were producing from one fifth to one third of the original amounts of sputum.

The effect on bacterial flora is summarized in table 3. The proper evaluation of these data is difficult for

of certain groups viridans streptococci pneumococci, Friedlander bacilli and the like are considered to be pathogenic although this cannot be proved with certainty without pathogenicity testing. The Neisseriae (flava siccra and catarrhalis) and the various bacteroids diphtheroids and micrococci are usually considered as secondary invaders, but this of course does not mean that they are innocuous or that they have no part in producing symptoms or tissue damage.

Table 3 also summarizes the alterations in bacterial content noted following from one to three instillations of a 5 per cent suspension of microcrystalline sulfathiazole as shown by cultures obtained bronchoscopically before and from twenty-four to forty-eight hours after the last instillation. The difficulties encountered in evaluating these data are the same as those already described.

⁹ Suggestions concerning evaluation of the bacteriologic data were given by Earle H. Spaulding, A.B. Ph.D., a lecture in bacteriology, Temple University School of Medicine.

COMMENT

The clinical data presented are intended as only a preliminary report, further study and observation will be required to confirm our impression that the measures described are of actual value. The general effect of sulfonamide compounds appears favorable, particularly when combined with a series of bronchoscopic aspirations. We have tentatively preferred the oral method of administration because of comfort and convenience from the patient's standpoint and because its use presumably allows a much more diffuse, uniform and prolonged action than can be obtained by instillation or a series of instillations.

The disadvantages encountered in the use of instillations are the following: 1. It is difficult to distribute the instilled material uniformly among the various diseased segments, even when the instillation is performed bronchoscopically. 2. Prolonged action can be maintained only by daily instillation, in the case of sulfadiazine aqueous solution, even this would fail to maintain sufficient amounts for continuous local effect. 3. The consistency of bronchial secretion appears to be unfavorably affected by instillation of sulfonamides, this change is particularly true in the case of microcrystalline sulfathiazole suspension which causes a rather definite increase in the viscosity of the secretion. 4. Local efficacy of sulfonamides is greatly diminished in presence of purulent material of the type produced in bronchiectasis, although presumably the addition of an oxidizing agent such as strong solution of iodine at least partially destroys the inhibitory effect¹⁰ of the para-aminobenzoic acid present in purulent exudate.

Untoward reactions were not observed in this study with one exception. One of the patients, a girl aged 17 years with bilateral sacular bronchiectasis, developed fever reaching 102 F the day following an instillation of 5 per cent microcrystalline sulfathiazole suspension. The temperature subsided promptly following bronchoscopic aspiration, and since the findings were not suggestive of a lobar atelectasis we believe that this temporary effect was due to transient occlusion of one or more of the segmental branch bronchi by thick secretion.

We hesitate to advance absolute indications for the type of treatment described. However, it would appear to be of definite value as a preliminary to lobectomy or pneumonectomy for suppurative disease. Here reduction in the amount of suppurative exudate from the diseased lung lessens the possibility of aspiration into the good lung at the time of operation and partially eliminates the risk of postoperative atelectasis or pneumonitis. Diminution of infection should likewise decrease the likelihood of postoperative empyema.

Riggins,¹¹ Perry and King¹² and others have amply emphasized the problem created by the morbidity of patients with well established bronchiectasis who fall into the nonsurgical group. These patients, if untreated, follow the natural course of the disease through a series of acute infectious complications to chronic disability and, usually, early death. The persistence of symptoms and progression of disease in bronchiectasis are due in the main to chronic infection. It has appeared to us that this factor can be most directly attacked

by combining a measure which improves bronchial drainage and prevents stagnation (bronchoscopic aspiration¹³) in a rather intensive course with specific antibacterial therapy. This means, in most cases, hospitalization for a period of from seven to ten days.

It is not possible to predict in advance which patients will obtain the most clinical benefit. For example, M. S., a girl aged 19 years with unusually extensive sacular bronchiectasis involving four lobes, had been producing approximately a pint of foul sputum daily. She was given a course of sulfadiazine by mouth for nine days and received four bronchoscopic aspirations during the same period. Her sputum was reduced to less than one fifth of its former volume, and although the cultures showed no qualitative change in the bacterial flora there was substantial decrease in the odor. More significant is the fact that during the six week period after leaving the hospital this patient increased her weight from 99 to 116 pounds (from 45 to 52.6 Kg.), more than she had ever weighed previously.

Undoubtedly the research programs now under way will produce specific antibacterial substances whose action will be more potent and toxicity less than that of the sulfonamides we have been using. Penicillin has already been found effective in acute phases of pulmonary suppuration in the three cases reported by Blake and Craige¹⁴. Castex, Capdehourat and Lavarello¹⁵ and more recently Harris, Sommer and Chapple¹⁶ have administered sulfonamides by inhalation. Further investigations similar to the one which has been attempted in this study will probably be warranted.

SUMMARY AND CONCLUSIONS

1. The concentration of sulfadiazine in bronchial secretion during oral administration is approximately 60 per cent of the blood level. This ratio is apparently not materially affected by the extent of bronchial disease or the amount of expectoration.

2. After intratracheal or intrabronchial instillation of 5 per cent aqueous suspension of microcrystalline sulfathiazole, significant concentrations persist in the bronchial secretion for twenty-four to forty-eight hours. The concentrations are larger, as would be expected, in cases in which there is but little expectoration.

Elimination of 2.5 per cent aqueous solution of sulfadiazine following intratracheal or intrabronchial instillation appears to be much more rapid, the amounts remaining at the end of twenty-four hours being negligible.

3. Combined sulfonamide and bronchoscopic treatment in 10 cases of acquired bronchiectasis resulted in a considerable reduction in daily sputum volume, with favorable alterations in the bacterial flora.

4. The plan of treatment described should prove of definite value as a preliminary to lobectomy or pneumonectomy for suppurative disease. It is probably worthy of trial in cases of well established non-surgical bronchiectasis.

SOME COMPLICATIONS OF CAUDAL ANESTHESIA AND THEIR MANAGEMENT

THOMAS G GREADY Jr, MD
CHICAGO

Recently there has been comparatively widespread and in some instances indiscriminate use of continuous caudal anesthesia in obstetrics. To prevent serious accidents, some of the hazards and the methods of preventing and combating them should be reemphasized.

As more data are accumulated, one learns of complications which might have been prevented had the proper safeguards been taken. Some of the complications presented followed the single injection rather than the continuous administration of the anesthetic. However, the same principles apply to the two groups.

In a series of 121 cases of caudal anesthesia at the Chicago Lying-in Hospital there have been no deaths, either maternal or fetal. However some interesting reactions have occurred, the most frequent being a drop in blood pressure. Our incidence of failures is 16 per cent.

SUBDURAL INJECTION

Most serious and dangerous of the complications is that of injecting the solution into the subarachnoid space, and it has only been recently that precautions other than simple aspiration have been taken to prevent this accident.

While no deaths have been reported due to this complication since the introduction of continuous caudal anesthesia, there have been serious accidents, and in 1920 Zweifel¹ reported a series of 4,200 single caudal injections with 10 deaths, 3 of which were attributed to the anesthesia, an incidence of 1 in 1,400. All 3 deaths occurred within a few minutes of respiratory failure, and in connection with 2 of them punctures in the dura were demonstrated at autopsy. The third was not investigated and was ascribed to acute procaine poisoning. About three years ago a similar accident was observed by Eastman². In approximately the one hundredth case of single dose caudal anesthesia in the obstetric service at Johns Hopkins Hospital a death occurred due to injection of 45 cc of 1 per cent procaine hydrochloride into the subarachnoid space although the usual precaution of aspiration was carried out. Chemical analysis of the spinal fluid post mortem showed a lethal concentration of procaine.

My associates and I have observed perforation of the dura once in our series of 110 cases. In this instance the needle was introduced into the caudal canal and on aspiration no spinal fluid was obtained. According to the routine advocated by Hingson and Edwards³ and Gready and Hesselstine⁴ a test dose of 8 cc of a 1.5 per cent solution of metycaine hydrochloride (120 mg) was injected and ten minutes allowed to elapse. (The importance of this simple precaution cannot be too strongly emphasized.) At the end of ten minutes the patient had almost complete paralysis of the dependent extremity but was still able to move the toes on the

opposite foot. In another two minutes there was complete motor paralysis of both lower extremities, while on the abdomen the anesthesia had risen to the level of the third thoracic segment. Since no spinal fluid was obtained by aspiration, it is apparent that had the precautionary measure of waiting ten minutes before injecting the 30 cc dose not been taken the procedure would have resulted in massive spinal anesthesia (approximately 450 mg in 30 cc), which probably would have been fatal.

Block and Rochberg⁵ report 1 case out of a series of 39 in which massive spinal anesthesia occurred. In their case 30 cc of a 1 per cent solution of procaine hydrochloride had been given. Fortunately the patient survived after a prolonged period of artificial respiration.

Small⁶ reported a similar case of possible massive subdural injection in spite of careful precautionary measures. He employed the continuous drip technique. Respiratory failure also developed.

Another such case has been brought to my attention by Brown⁷. In this instance a single caudal injection had been made for a proposed cesarean section. The patient survived spinal anesthesia high enough to cause both respiratory and vocal paralysis. These near catastrophic results illustrate the importance of combining preliminary aspiration with a suitable test for subarachnoid injection. Hingson and Edwards³ reported that perforation of the dura had occurred only twice in more than 1,000 injections.

The best treatment for this unwelcome accident is prevention, and the test dose I believe is the best method available to avoid a massive subdural injection. It is further recommended that a test dose of 5 to 8 cc be repeated ten minutes prior to each subsequent injection. This is especially important when the needle technique is used, since the needle may pierce the dura at any time during the procedure. This apparently occurred in the case reported by Small.

A thorough knowledge of the normal anatomy of not only the bony sacrum and sacral canal but also the dural sac and spinal cord is important and indeed fundamental if one is to administer caudal anesthesia intelligently and safely. The spinal cord normally ends at the level of the first lumbar vertebra, with the dural sac containing spinal fluid and the cauda equina tapering to a point in the sacral canal at the level of the second sacral vertebra. The contour of the lower end of the dural sac is not constant but varies with straining, jugular compression and other forces, as has been shown by x-rays after introduction of opaque substances. The sacral canal is continuous with the epidural space in the vertebral canal and extends all the way to the foramen magnum. Anatomic variations in the sacrum are common and may at times interfere with the proper insertion of the needle.

The important fact that the dural sac may extend lower than the second sacral vertebra should be kept constantly in mind. If the patient is thin and the sacrum short, the use of a 2½ inch rather than a 3 inch needle lessens the danger of perforating the dura. This complication also seems less likely when the catheter method is used. There is a continuation of the dura around each of the nerves in the sacral canal for a variable distance, as can be seen in the illustration.

Fl. Lilly & Co. furnished the metycaine used in this study. Dr. William J. Dieckmann and Dr. H. Cloos Heffeltine gave helpful criticism of the manuscript.

It is theoretically possible for the point of the needle to pierce this dural sheath thus permitting the injected solution to dissect up into the subarachnoid space. Such a puncture of this nerve sheath and subsequent injection may cause pain and so give some warning.

Should the recommended precautions be disregarded and massive spinal anesthesia occur, treatment should be instituted immediately. The patient should be supported in a sitting position, and a lumbar puncture should be done using a large needle so that the fluid will flow rapidly. Walker⁸ recommends that approximately 100 cc. of spinal fluid be withdrawn. The flow can be hastened by compression of the jugular veins.

Diagram showing the relationship of the dura mater and cord to the epidural space and to the sacral and the vertebral canal (after Toldt Karl, *Atlas of Human Anatomy*, New York, Macmillan Company, 1926)

in the neck. Forced drainage may also be accomplished by giving 0.45 per cent saline solution intravenously while the lumbar puncture needle is in place. Hypertonic dextrose solution would decrease the amount of spinal fluid and thus retard drainage. It is extremely important that the fluid be drained off before the drug has reached the vital centers in the brain. Even though the respiratory center is anesthetized, the method should still be tried in order to prevent involvement of the vasomotor center, which is at a higher level. Drop in blood pressure and shock are combated in the usual manner with ephedrine, stimulants and intravenously injected fluids, such as plasma. Respiratory paralysis must be treated by artificial respiration. The presence of a physician anesthetist skilled in the art of intubation and resuscitation might prove life saving, as it undoubtedly did in 2 of the cases reported.

INFECTION

Because its appearance is usually delayed, infection is sometimes overlooked as a complication of caudal block. It ranks second in importance to massive spinal anesthesia. It may occur either in the tissues outside the sacral canal or in the epidural space. The latter is more serious because of its proximity to the cord and nerves of the spinal and sacral canal. It may be extremely dangerous and even cause death. That the epidural space is much more susceptible to infection than the subarachnoid space is suggested by experiments on monkeys. Cultures of virulent organisms were injected directly into the spinal fluid without causing any evidence of inflammation.⁹

Edwards and Hingson¹⁰ recently reported a death from infection in a series of 650 obstetric cases. An epidural abscess developed with which there were no localizing signs or neurologic manifestations. The patient was treated with sulfonamides but died on the thirty-first postpartum day. Post-mortem examination revealed multiple small pulmonary abscesses and a large abscess involving the peridural space and communicating through the foramina with a subpsoas abscess. The infection had not penetrated the meninges.

Carlisle¹¹ reported a death following continuous caudal anesthesia of a patient aged 70. After laparotomy a large necrotic, sloughing ulcer developed over the sacrum which extended to the bone. Death on the twentieth postoperative day was believed to have been due to this infection. However, since autopsy was not permitted it is not known whether or not the epidural space or the meninges were involved.

Siever and Mousel¹² in their series of 300 cases had 1 case of epidural abscess. They report "the patient was seriously ill for three weeks but responded to large doses of sulfonamide compounds and completely recovered."

Manalan¹³ reported staphylococcal meningitis occurring after 1 of 46 single caudal injections made with the catheter technique. On the third postpartum day symptoms of malaise, headache and hyperirritability developed. No local infection in the sacral canal could be determined by aspiration. The statement is made that "she recovered completely following a critical illness."

The complication was believed to have been due to sacral block, but this was never proved.

In 1927, following an attempt at sacral block, Hall¹⁴ reported a death from gas bacillus infection. Southworth, Edwards and Hingson¹⁵ reported low grade cellulitis about the sacral hiatus in 1 case in a series of 355.

The principal etiologic factor in this type of case is obviously faulty technique. Extreme care should be taken in the sterilization of the apparatus and in the preparation of the solution. The site for injection normally is not the cleanest part of the body, situated as it is close to the anus. It should be as thoroughly cleaned and prepared as for a major surgical procedure. Rigid asepsis is of the utmost importance. If the needle technique is used, the only bacteriologic weak point in the equipment once the tubing is connected is the plunger of the syringe. Since the anesthesia is sometimes carried out over a period of hours, it is not at all improbable that during one of the many injections the plunger may be accidentally contaminated and then on a subsequent injection bacteria may be introduced into the sacral canal.

Symptoms of epidural abscess at first are those of systemic infections in general, such as malaise, fever and leukocytosis. According to textbooks,¹⁰ the symptom which first focuses attention on the spinal region as the site of infection is usually pain in the back, which may be exaggerated by coughing, sneezing, jugular compression or movement of the spinal column. There also may be tenderness over the spine in the region of the abscess. Radicular pains at the site of the abscess are common, and there may be hypesthesia or numbness in the dermatome supplied by the nerve roots involved. If the abscess is situated in the lumbar region, spinal puncture should not be done because of the danger of penetrating the abscess with resultant contamination of the subarachnoid space. Bagley and his co-workers¹⁶ recommend surgical drainage as soon as the diagnosis of abscess is established. This often necessitates laminectomy. Accessory measures, such as the use of sulfonamides, blood transfusion and the injection of a specific antitoxin, should be employed. Siever and Mousel¹² treated their patient with sulfonamides alone. She survived. The help of a competent neurologist may be of much value in locating the site of infection.

Local infection about the site of injection does not present such a problem as infection in the epidural space. There the management is the same as for other superficial infections. In our series so far we have had no infection of the epidural space nor have we had any local infection of the skin.

INTRAVENOUS INJECTION

Intravenous injection of the drug is another complication which cannot always be avoided. The minimum lethal intravenous dose of procaine in animals has been found to be one-tenth the amount necessary to kill the animal if given subcutaneously.¹ Preliminary aspiration must always be carried out to minimize this danger. If blood is obtained the position of the needle must be changed until blood can no longer be aspirated and then the injection should proceed slowly and expectantly. We have had 1 case in which this complication occurred. In this instance no blood appeared on preliminary aspiration, and with the patient in the knee-chest position the 8 cc test dose was administered. The patient was then turned on the left side. In ten minutes

25 cc of a 1.5 per cent metycaïne hydrochloride solution was injected. The patient immediately became irrational, talked incoherently and underwent mild clonic convulsions of both upper and lower extremities. Slight opisthotonos was present. This reaction lasted about two minutes and disappeared spontaneously before treatment could be instituted. We are certain that the fluid went intravenously for three reasons: (1) The needle and approximately 1 foot of the pressure tubing was found to be filled with blood, (2) absolutely no anesthesia developed although a total of 33 cc of the drug solution was injected, (3) the needle was reinserted and the caudal anesthesia carried out successfully and without reaction for the remainder of the labor. Possibly the 5 patients reported by Lahmann and Mictus¹⁸ as becoming "irrational" and developing 'clonic convulsions' received a certain amount of the drug intravenously. In these cases the reactions also passed off in a few minutes without serious effect. Cases are on record, however, in which intravenous injection of procaine has proved fatal. The toxicity from these drugs can be due to three factors: (1) rapid absorption, (2) intravenous injection and (3) idiosyncrasy. In richly vascular areas, such as the epidural space, rapid absorption is likely to take place.

Treatment for the condition is more or less specific and is the same as that for an overdose of the drug. The excellent work done on the toxicity of cocaine by Tatum, Atkinson and Collins¹⁹ using rabbits and dogs, proved that the various barbituric acid derivatives are of distinct value both in prophylaxis and in treatment. They showed that the prophylactic administration of a mixture of barbital sodium and paraldehyde to the dog raised the minimum lethal dose from 267 mg per kilogram to above 100 mg, representing approximately a fourfold increase in tolerance. In severe reactions due to overdosage, death may occur from either paralysis of the heart muscle or respiratory paralysis during a convulsion. It is imperative that respiration be maintained, by artificial means if necessary. One of the quick acting barbiturates, such as evipal sodium or pentothal sodium, should relieve the convulsions immediately. When caudal anesthesia is used, it is wise to have one of these drugs readily available. In our case the reaction had disappeared by the time the drug was prepared for administration, so it was not given. Since the barbiturates counteract the untoward effects of the local anesthetic, the administration of one of them is indicated as preoperative medication when this type of anesthesia is to be used. Rapid absorption may be delayed by the addition of epinephrine to the solution.

IDIOSYNCRASY

Sensitivity to locally employed anesthetic drugs may occur, one of the most dangerous types being that manifested in the anaphylactic reaction. Every patient should be questioned prior to the initial injection as to a history of allergy and especially as to previous reactions to these drugs. Practically every patient has had a tooth pulled at one time or another under local anesthesia. If a reaction occurs its management should be the same as for any other anaphylactic reaction, namely the immediate hypodermic administration of

epinephrine hydrochloride. Convulsions, should they occur, are controlled by using barbiturates intravenously, care being taken not to give an overdose.

INJURY OF NERVE ROOTS

Judging from the paucity of reports in the literature, injury of the nerve roots in the caudal canal does not often occur. I report some observations from a case which occurred in Hawkins's²⁰ practice in Chicago.

With the needle technique continuous caudal anesthesia was maintained for nine and one-half hours. A total of 215 cc of a 1.5 per cent metyline hydrochloride solution was given. The second postpartum day the patient complained of pain in the region of the sacrum, numbness and numbness of the left great toe and anesthesia of the perineum. When the patient was allowed to be up she continued to have saddle anesthesia and complained of numbness and burning in the region of the great toe. Her gait was definitely affected with a tendency to place the right foot forward much like a diabetic patient. Two months later she was again seen by a neurologist who reported: "There is slight difficulty in hopping on the right foot and she can walk on her toes better than on her heels, gait and station are not otherwise affected. There is rather marked weakness of the anterior tibial and peroneal muscles on the right side and of extension of the toes. There is slight weakness of the muscles of the right calf and of plantar flexion of the feet and toes. Some impairment to pinprick was present over the right foot on both dorsal and plantar surfaces. There was also slight hypesthesia to pinprick in the saddle area bilaterally. This patient presents evidence of injury to the fourth and fifth sacral roots bilaterally and to the first sacral and fifth lumbar roots on the right side."

From the history, improvement was taking place and the prognosis for ultimate recovery was believed good.

BREAKING OF THE NEEDLE

The complication of a broken needle has not yet occurred in our series, although of necessity we have used some needles more than five times. Hingson and Edwards²¹ reported 12 cases of broken needle out of a series of 850. In 4 instances a small incision was necessary for removal. Their last 250 consecutive procedures were done without a break. Block and Rotstein²² were unable to remove a broken needle from the canal, so they left it in place.

A broken needle should be removed immediately lest it migrate farther into the sacral canal and become inaccessible.

Cathelin²³ reported a case in which the needle fragment was recovered from the body of the fourth lumbar vertebra at autopsy six months later, and Meeker and Scholl,²⁴ a case in which removal of the posterior wall of the sacrum was necessary to recover the needle.

The incidence of this complication has been considerably reduced since the development of the malleable needle and catheter technique. The danger can be still further minimized by keeping the patient on her side during labor and then giving an injection and removing the needle just before she is placed on her back for delivery. It is suggested that the needle not be withdrawn until the obstetrician is certain that the cervix is completely dilated and the patient ready for delivery.

CHANGES IN BLOOD PRESSURE

Mild and severe vasomotor reactions developed more often than has been reported by most investigators. Shaw²⁵ in 1925, however, using the single injection method in urologic practice, described changes similar to those which my associates and I have observed.

The relaxation of a patient in labor, after the pains have been relieved and the anxiety has subsided, usually causes a slight fall in blood pressure. Fifteen patients had slight chills and complained of having the "shakes" but not being cold. Such complaints represent a mild vasomotor or toxic reaction. Preliminary administration of a barbiturate may prevent it. In our group of cases there were 27 with a drop of more than 20 mm in systolic pressure. Usually such a change is associated with a feeling of faintness, fatigue and sweating. The face is pale and the pulse weak. Increased respiratory excursion may indicate mild air hunger. One patient complained of severe substernal pain. All the larger changes in blood pressure occurred in patients in whom the level of anesthesia was at or above the umbilicus. The changes undoubtedly were due to splanchnic dilatation as the visceral sympathetic fibers were blocked. Of 39 patients with an anesthetic level at or above the umbilicus 26 showed drops of more than 20 mm. Two patients definitely had shock reactions, the systolic pressure dropping to zero from 158/110 and 90/60 respectively. In 2 instances slowing of the fetal heart rate was noticed during the period of lowest pressure. Every one of these patients responded to ephedrine sulfate administered hypodermically and oxygen inhalations. In 19 patients the anesthesia was pushed to a high level in preparation for cesarean section. The drop in blood pressure could have been minimized in this group by preliminary administration of ephedrine. Patients with severe heart disease probably would not tolerate the increased cardiac load associated with large drops in blood pressure.

Control of dosage to prevent too high a level of anesthesia should eliminate this reaction in most patients during labor. The semi-Fowler position or elevation of the head of the bed tends to keep the anesthesia at a low level whereas the Trendelenburg position favors an ascending level. Possibly the addition of epinephrine to the solution would also prevent large drops in pressure.

ANTESACRAL INJECTIONS

Owing to variation in the type of sacrum and in angulation of the coccyx it is possible in difficult cases to penetrate the sacrococcygeal joint or the tissue lateral to it so that the point of the needle comes to rest on the anterior surface of the sacrum close to the rectum. This has occurred twice in our series. In both cases there was difficulty in identifying the sacral hiatus. One of the patients had evidence of rickets. In cases in which the anatomy is obscure, preliminary rectal examination with palpation of the sacrococcygeal joint is helpful in preventing this error. If the infant's head is low, it is conceivable that the rectum flattened against the sacrum may be penetrated. The accident occurs more frequently with beginners and in most instances represents carelessness.

COMPARISON OF METHODS WITH REFERENCE
TO COMPLICATIONS

Two principal methods are advocated for this type of anesthesia, the malleable needle technique originated by Hingson and Edwards and the catheter modification described by Adams, Lunde and Seldon²⁶ and Manalan.¹³

Since we have used only the malleable needle technique we do not have two series to compare, however logically, different methods are devised because they avoid certain complications.

The advantage of the catheter technique aside from the fact that it allows greater freedom of movement on the part of the patient is that there is less danger of perforation of the dura or a blood vessel once the needle is withdrawn over the catheter. Three disadvantages are apparent: (1) There is more trauma associated with the introduction of the 13 gage needle, (2) this trauma naturally increases the risk of infection, (3) the number of failures should be increased, owing to the difficulties involved in the insertion of the large needle in some patients.

With use of the needle technique the complications which are increased in number are (1) the perforation of the dural sac after the needle is in place with subsequent intraspinal injection, (2) the broken needle and (3) the possible trauma inside the canal if the needle is manipulated by the patient moving about on her back.

The development of a smaller useful catheter which can be threaded through a 16 gage needle should combine the advantages of the two methods with resulting increased safety.

DO NERVES BECOME REFRACTORY TO LOCAL
ANESTHETIC DRUGS?

In general, we have noticed some difficulty in maintaining the effect of the anesthetic that is used over a long period of time. This same observation has been made by Wall²⁷ and may be due to malposition of the needle. However, the thought has occurred to us that possibly the nerve roots may become refractory to the action of the drug after prolonged anesthesia. We have noticed this phenomenon in 3 cases in which we felt certain that the needle had not become dislodged from its proper place in the caudal canal.

Regnier and Lambin²⁸ noticed a disappearance of the anesthetic action of dilute solutions of cocaine hydrochloride after prolonged instillation of these on the cornea of the rabbit. The possibility of this occurring in peripheral nerves should be investigated.

First Description of Pulmonary Circulation—Around the middle of the thirteenth century an Arabic physician, Ibn an-Nafis described the pulmonary circulation. This is the earliest description we know, and its rediscovery has put an end to the claims for priority of either Michael Servetus (1553) or Realdus Columbus (1559). However, it is not probable that Servetus knew of his Arabic predecessor nor has any historical link been established between Ibn an-Nafis and Columbus. Whether on the other hand any connection existed between Servetus and Columbus is a question still open for debate—Jarker, Sanford V, and Temkin Owen in *Essays in Biology* Berkeley University of California Press 1943.

DEFINITIVE TREATMENT OF
SEVERE WOUNDS

LARGE SURFACE TO SMALL AREA

COLONEL JOHN L. GALLAGHER
MEDICAL CORPS, ARMY OF THE UNITED STATES

It is generally understood that the first aim in the practice of surgery and medicine is to get the patient through an ordeal alive, at all times keeping him at the greatest possible distance from the possibility of death. From the surgical standpoint this aim is achieved when the patient arrives at the hospital as a good risk. Yet often the traumatic patient arrives at the hospital in extreme shock, even irreversible shock, when if adequate first aid had been given promptly after injury he would have arrived at the hospital in good physical condition. For example, a patient arrives practically exsanguinated by profuse hemorrhage from an otherwise minor wound, the hemorrhage from which could have been readily controlled by a compression dressing. Similar mischances are usual in all forms of injuries whether they are surface wounds involving extensive areas of the body, crushing injuries of moderate areas or severed blood vessels in small area wounds.

The medical profession has made great strides in the care of these patients at the hospital, but it is my belief that a great deal more can be done for patients with traumatic injuries during the critical period from the time of injury to the time of admission. Since the care of the patient prior to admission to the hospital is in the hands largely of nonprofessional and only briefly trained persons, treatment must be outlined which will be simple in procedure but most effective in functional result. This prehospital treatment should be such that its principles will be carried on into and through hospitalization. It is to this goal that the present paper is directed.

To illustrate my meaning better, a number of cases are presented.

Approximately one year ago 22 men were working in a building about 20 by 30 by 10 feet. This building became filled with gasoline fumes, which ignited, resulting in a violent explosion followed by a total fire. Two men were blasted from the building through the only door one of them receiving a second degree burn forming a 4 inch band around the lower third of the left leg. Otherwise there was no injury to these 2 men. The negative pressure created by the blast slammed the door shut. The inside of the building became entirely aflame, and the 20 men remaining in the building received fatal or serious flash type as well as slow type burns. It was not possible for any of the remaining men to get out of the building until the fire department arrived, broke in the door and had the fire under control. In the following confusion 2 of the severely burned victims slipped out of the building ran to a small hospital 3 blocks distant, went into irreversible shock and died without responding to shock treatment. Four were dead when found and 2 died immediately after reaching the hospital. Except for the 2 men who ran from the building the patients were placed on litters and conducted to the hospital by ambulances. This particular hospital had only one operating room and an emergency treatment room necessitating the use of improvised operating rooms.

In accordance with hospital rules all attendants immediately took cap mask and gown precautions and by medical officers orders gave every patient ½ grain (0.032 Gm.) of morphine sulfate subcutaneously. The dead dying and critically injured practically filled the hallway of the small hospital where they had been placed by the ambulance crews at the direction of the attending surgeon. The stench of the burned human flesh

and clothing added to the horror of the continual cries of pain. The doctors and the nurses present administered morphine to the living and gradually the patients became quiet.

There was a selection made for priority in operation in that the moribund patients were held for shock treatment. The force was divided into teams with each of the most experienced surgeons having an assistant medical officer and nurse. Each team immediately started blood plasma intra-

patient was close to exsanguination but was conveyed to the operating room, where he was given plasma, a large blood transfusion, and treatment for shock for two hours without molestation of the dressing. Then, with everything ready, his wound was repaired. He was given another transfusion during the night and still another the next day, following which he progressed to complete recovery.

This case is unusual in that the compression dressing, although at hand, was not used promptly by the excitable attendant. The dressings have been successfully used promptly by personnel in every other similar case in some of which the tourniquet would have been as here, of no avail. Such instances clearly illustrate what compression treatment can do for profusely bleeding wounds. Had this dressing been used by the ambulance driver as he had been thoroughly taught to use it, it is reasonably certain that the patient would not have been so near to dying. Had the distance to the hospital been longer the patient would have arrived dead.

DESCRIPTION OF NEW TYPE DRESSINGS

All five of the first aid dressings described herein embody the compression technique. The original type dressing (labeled *B* in figure 1) was made to simulate the sea sponge as it would be dampened and all ready in moderate compression. The economy of space gained by packing is illustrated by comparing *A* and *B* in figure 1. The new package as reduced by hand pressure only will be smaller when packed by machinery. The new dressings are made to comply with a demand for a more compact packaged dressing to avoid waste space in shipment and to permit the first aid men to carry a more adequate supply in small first aid bags. These dressings when adequately packed, as by machinery will occupy but little more space than a package of cigarettes, but when released they will have adequate bulk in great depth to cover an area approximately 4 by 4 inches while still in the sponge shape, and when further unfolded, by pulling the short string, they will offer a cover type compression dressing of 36 square inches. The larger dressing is similar to the smaller one as shown in figure 2 *C* except that it has a bias cut stockinet bandage anchored to its top. It can also be press packaged for economy of space, but when

Fig. 1.—The reduction in size of the packaged dressings (1 new type original) will be more pronounced when the new type is packed by machinery. *A* is the new dressing as represented in figure 2. (Official photograph U. S. Army Air Forces Technical Training Command.)

venously and where necessary, cutting down on the vein. They then proceeded to cleanse the wounds with sterile water and sterile whipped white soap, lavaging away the white soap with sterile cotton that had been saturated with saline solution. Then with sterile spring forceps, sharp dissecting scissors or Bird-Parker knives complete debridement of all wounds was accomplished.

The use of tannic acid-silver nitrate on the trunk and the upper half of each arm was necessary because there was not adequate compression dressing material on hand. If another similar disaster should be encountered, the compression technique would be used entirely, for it is now seen that sufficient materials are on hand.

It is believed that the patients discussed here were well handled under the circumstances in that all who did not die within fourteen hours recovered to return to full duty. However, it is probable that under the present day management of first aid treatment to the severely burned, had this disaster happened at a considerable distance from the hospital, practically none of them would have survived. The 2 men who ran from the scene of the fire to the hospital and went into irreversible shock illustrate the point clearly. Figures 3 to 8 present a comparative case.

To illustrate the first aid treatment of profusely bleeding wounds by the compression principle, another case is briefly discussed.

A civilian employee was painting lines in an airplane parking area of an airport, when an airplane out of control ran over him. The propeller of the airplane struck him at the right midclavicular area, widely opening his thoracic cavity at the apex. An ambulance driver, parked within a few feet of the accident, rushed over with his ambulance, picked up the injured man, placed him on a litter, saw his profuse bleeding but only became more excited by seeing it, and although there were ample compression dressings in the ambulance, raced madly 6 blocks to the outpatient department of the hospital without applying the dressings. An attendant there saw the profuse hemorrhage, grasped a large packaged compression dressing, ripped off the top of it, placed it on the wound, applied compression with the bandage going under the opposite arm pit, thereby forcing the pad down into the apex of the right chest cavity, and effectively stopped the hemorrhage. The

Fig. 2-4, new type packaged dressing made impervious by waxing. *B*, dressing with the pressure cap not completely drawn up. *C*, dressing with long string which when pulled leaves the pad ready for use, simulating a sea sponge of great depth. *D*, dressing unfolded to cover 36 square inches in good compression. The large dressing unfolds to cover 81 square inches. (Official photograph U. S. Army Air Forces Technical Training Command.)

released from its compressed package it will have its original large bulky sponge of great depth for safe control of external hemorrhage from large wounds, up to 5 by 5 inches plus the advantage of an elastic bandage for holding the dressing to difficult contours, e. g. those of the head and shoulders and the groin, with a more

resilient compression This dressing when unfolded by pulling the short string will cover an area of 81 square inches and retain its compression feature

My pack for compression treatment of all extensive wounds and for Koch treatment of burns consists of sixteen sterile pads 9 inches square, each pad containing 8 ounces (225 Gm) of grade 1 mechanic's waste,

Fig 3—Patient injured in a gasoline explosion and fire. There were third degree burns of the zygomatic area of the face, of the nose and both ears the anterior surface of the neck the anterior surface of the chest the anterior and lateral surfaces of the upper half of each arm and of the shoulder and of the forearms and the hands. The remainder of the face including the upper eyelids the mouth and the chin showed second degree burns. The aforementioned areas were bordered by wide areas with first degree burns. The primary treatment was completed within two hours after injury. (Photograph by U S Army Air Corps)

covered by one thickness of 44-40 mesh gauze overlying two layers of coarse gauze. Four of the dressing pads have a 5 inch by 5 yard roller bandage of bias cut stockinet anchored to them. The pack also contains two operating caps and three face masks (the extra mask for the face of the patient). The entire package is put up in maximum compression for the purpose of economizing space in shipment to armed forces and in carrying by personnel and to permit hospitals generally to maintain adequate sterile supplies of the dressings for disasters. The final container will be tin 8 by 8 inches. Thus in this small cube there will be adequate, smooth, soft, compressible, sterile surgical pads and elastic bandages to cover 1,296 square inches of body surface (both upper extremities, shoulder girdles and axillas) and also finger individualizer strips, caps and masks. It is further proposed to place instructions on the outside of the package for the handling of severe wounds (burns and other types) in this manner. The principal ingredient of these dressings is mechanic's waste (cotton waste) a waste thread material from textile mills and therefore most inexpensive and plentiful. Grade 1 of this material can be bought in Chicago for 9 and a fraction cents a pound. Compare this price with that of absorbent cotton or that of surgical gauze and the economy will be apparent. From the standpoint of resilience mechanic's waste is the one adequate substitute for the unobtainable sea sponge. Neither absorbent cotton nor waste cotton nor surgical gauze can compare with mechanic's waste in the all important matter of giving resilience to compression dressings. It is a fair absorbent and is readily sterilized.

When firm, safe bandaging is applied over a wound coverage such as this, with ample bulk and good resilience, the dressing continues to cover the wound indefinitely, whereas a dressing of poor resilience will slide off the wound or turn to expose it, even if the bandage is applied so tightly as to cause constriction. This is particularly true when there is a circular bandage about an extremity or the thorax, where there is a constant

change in the circumference. If there is a bulk of resilient material beneath the bandage, it will give as the bandage tightens and will spring back to take up the slack as it loosens to hold the dressing firmly in place. If, on the other hand, there is not resilience in bulk, the dressing pad becomes packed, or the threads of the bandage give (something must give if there is not ample resilience), and the dressing loosens and slips from the wound. This feature of the resilient bulk of the dressing giving when the circumference of a portion of the body increases is an important safety factor in that it prevents a circular bandage about an extremity from accidentally becoming an effective tourniquet subsequent to enormous edema formation or when an arm or a leg becomes flexed after application in an extended position. It is difficult to obtain constriction as one bandages over a bulky dressing of good resilient material when the bandage is going on smoothly in one direction. However if there are two bandages being applied in opposite directions with each offering force for the other to be pulled against, constriction is likely and gangrene of a member is a real danger.

This entire series of dressings has been devised with the thought of simplifying for nonprofessional or briefly trained personnel, prompt optimal first aid treatment for the injured. This procedure will enable such personnel to apply efficient, effective dressings, which can be applied by them and maintained in their aseptic condition. The dressing when so applied will serve to control bleeding without the use of the tourniquet, give compression therapy to the wound area, bring about a splinting effect to the wound so pad an extremity that a hard rigid splint can be applied without further padding and give protection from outside contamination by the sterile bulk of the dressing. Thereby many of the things which cause the patient to go into shock and on into irreversible shock are arrested early and a safe definitive treatment is instituted. The urge to rush is abated and the many injuries done to the patient in frantic haste to get him to the hospital are avoided.

Fig 4—Two days after injury. The patient is in a canopy bed. The sheets pillow case and other material reflect a sterile technique. All visitors and attendants are required to comply with cap mask and gown regulations. As shown the entire head the upper part of the neck the fore arms and the hands have voluminous compression dressings of cotton waste. The ears are fixed with supersaturated absorbent cotton molds. The eyes have been treated with yellow mercuric oxide ointment beneath the bandages. The remainder of the body (chest neck and upper arms) has been given the standard tannic acid silver nitrate eschar. (Photograph by U S Army Air Corps)

The patient who would otherwise arrive at the hospital in critical condition because of avoidable shock will arrive there in good shape with the fundamental principles of treatment already under way.

The advantages of the described compression dressings may be summarized as follows: (1) They control hemorrhage from the wound and thus the use of the tourniquet with its hazards, tedious timing and releasing is avoided, and more important they control hemorrhage from wounds where the tourniquet is not applicable,

to prevent shock from hemoconcentration occurring after extensive surface wounds or crushing injuries. Since fluid escaping into the tissues and remaining there as edema will result in the tissue cells being placed in a nonconductive medium, which also seriously compresses them and isolates them from the principal functions of the blood, namely (a) oxygenation, (b) nutrition, (c) phagocytic action and (d) elimination of waste products, the prevention of this series of events is to be desired.

It is firmly believed that the additional loss of skin experienced in the tannic acid-silver nitrate method of treatment of severe burns is mainly due to the aforementioned deprivation of the circulation and only slightly to the chemical action of the astringents. The cells which die do so largely because of anoxia of the tissue cells, but infection resulting from delayed phagocytic action also plays a part. Loss of nutrition and failure of elimination of waste products from the cells are due to the abnormal pressure and physiologic isolation resulting from surrounding edema. This theory is substantiated by the fact that severe burns often become infected whatever type of topical application is used unless the compression technique is employed. It is well known that infection rarely occurs when burns are promptly and properly treated by compression, whether or not a medicinal preparation is placed on the burned surface. The rapid improvement of a burned infected surface following compression treatment further substantiates this theory.

The modern concept that a burn is a large surface traumatic wound is of paramount importance in present day treatment. The extensiveness of the wound makes it more hazardous from the standpoint of infection than the ordinary traumatic wound, since there is more surface to receive contamination and a greater area over which the cells of the blood must be distributed in their phagocytic action against invading organisms.

(2) they insure ease and rapidity of aseptic application of primary adequate dressings by the nonprofessional attendant, (3) they facilitate application of dressings to dependent parts, as the under surface of the arm, the groin or the under surface of the chin, (4) they bring a splinting effect to the wound and its immediate area, (5) by pressure they prolong viability of tissue through aiding return circulation from the wound, (6) they obliterate spaces and crevices in wounds by this compression, (7) by their sterile bulk they form a barrier against added contamination, (8) they create a safety factor in that they may remain as originally applied without additional adjustments or changes for a number of days when necessary, as under battle conditions, (9) they permit easy, as well as efficient, application to any wound with or without spurting vessels under such unfavorable conditions as high wind, semidarkness and cramped close spaces as in multiple passenger combat planes, (10) they make a superior type of first aid treatment available at or near the scene of injury for extensive surface injuries, such as burns, frozen members (frost bite), severe abrasions or crushing injuries, and (11) they afford a dressing the bulky resilience of which will give maximum comfort and permit firm safe bandaging, adequate to hold it indefinitely in place.

PRINCIPLES OF THE COMPRESSION TREATMENT

It is my opinion, substantiated by outstanding surgeons of my acquaintance, that the compression treatment of burns is by far the most logical and successful. My own particular theories as to the success of compression treatment for wounds, whether burns, frost bite, traumatic or surgical wounds, are discussed briefly. The compression aids return circulation from the wound and in so doing tends to prevent edema. In an extensive surface wound, such as a burn, plasma is lost from the blood stream by escape into the tissues, the principal loss being into the tissues and not as formerly thought entirely out of the body by evaporation and drizzle. It is therefore most important that the compression treatment be instituted at the earliest possible moment

Fig. 6—After ten days the dressing is removed from the head of the right forearm and the hand. Note the absence of edema of the surgically clean wounds of the head, upper part of the neck and right forearm. The left ear is surgically clean, although bleeding slightly after removal of the dressing. The patient begged that the dressing of the badly lacerated left forearm and hand not be disturbed since it was so comfortable. (Photograph by U. S. Army Air Corps.)

Prompt precaution against contamination is indicated whatever the nature of the injury, and the greater the raw surface of the wound the greater the need for promptness in adequate protection. With extensive surface injuries, such as burns, severe abrasions,

multiple lacerations, the need for prompt protection against added contamination is even overshadowed by the need to get the wound under adequate treatment. Certainly when such treatment, if initially applied can serve as a control for severe hemorrhage from the external wound, as a protection against added con-

therapy should be accomplished prior to departure. The patient should not be subjected to transportation if he is developing shock until it is controlled, else it is likely to continue into irreversible shock and subsequent death.

RECOMMENDED PROCEDURE

It is proposed that an adequate simple sterile compression dressing be applied to a severe burn or other large surface wound immediately at or near the scene of injury, especially if the patient is to be moved a considerable distance. The technique is not involved. The persons administering the treatment obtain the multiple pad pack. They remove the top covering and put on the caps and masks taken from the pack. They then apply the patient's mask. Their hands are washed in soap and water followed by alcohol. The patient is given morphine sulfate $\frac{1}{4}$ to $\frac{1}{2}$ grain (0.016 to 0.032 Gm) subcutaneously and the first unit of plasma and the chemotherapy are started. The wounds are exposed by cutting away clothing as indicated, and every effort is made to keep the patient warm if the outside temperature is low. The plywood frame which opens to form a splint is then removed from the top of the pack. The draw string is pulled from the end of the muslin bag, presenting two finger individualizers. The first pad will be lifted off by its attached bandage and will be placed on one extremity of the wound. Then subsequent pads will be obtained, placed side by side and

Fig 7—Patient whose chest ears nose and zygomatic areas were apparently burned to about the same degree as he appeared eighteen days after injury. Notice how much further advanced toward recovery are the head forearms and hands comparatively. (Photograph by U S Army Air Corps.)

tamination and as a preventive of edema with its harmful effect on cellular metabolism, it will be advantageous to start this treatment early. To start treatment prior to contamination is the ideal. However, if contamination has already taken place it is of utmost importance to get this treatment under way (1) before the contamination becomes an actual infection, (2) before the increasing loss of fluid from the blood stream causes hemoconcentration with progressive shock and (3) before the fluid elements of the blood have escaped into the tissues to affect adversely cellular metabolism. Compression dressings on burns of the arms, the legs and the trunk, when approaching the total area of these members, help to raise the blood pressure of the patient in shock by compressing the blood vessels in the area and displacing the blood to the larger vessels and the heart for a more favorable volume. I have seen severely burned patients who already were suffering with shock react favorably immediately after the application of such compression dressings to the entire upper and lower extremities.

Many lives can be saved if optimal treatment will be given patients having severe or extensive wounds before they are subjected to transportation. (When indicated, treatment should be continued while en route.) Prompt effective control of external hemorrhage, proper compression dressing and splinting of all severe wounds, administration of a sedative, intravenous injection of plasma and institution of chemo-

Fig 8—After thirty five days some areas in the portion that received open treatment require a skin graft. The left ear has cupped a little but the deformity is not a noticeable one. There have never been indications of infection or edema or complaints of pain in the areas treated by voluminous dressings. None of these areas have any indication for skin grafting. (Photograph by U S Army Air Corps.)

fixed with the bandage under moderate pressure. The fourth pad will have another bandage and so on until the package is used up. Other packages are obtained as needed for complete coverage of wounds in compression. The splints from the frames may then be applied without padding.

The fine mesh 44-40 gauze in my opinion is the ideal substance for contact with the wound. If loose gauze is placed on the wound it should be saturated with isotonic solution of sodium chloride to keep it smoother as in the Neal Owen method. Here the gauze is held smooth by the pad to which it is attached. It is my belief that ointments, dyes, topical antiseptics and the like are harmful in certain instances and superfluous in most. However, chemotherapy given orally or intravenously is essential.

These dressings on burns of patients arriving at the hospital should remain undisturbed as treatment unless there is information on the diagnosis card or otherwise of gross debris, which would necessitate cleansing, debridement and subsequent reapplication of a compression dressing. Otherwise, to change dressings would subject the patient to added hazards of contamination and perhaps increase his shock. The compression dressings on lacerated and other severe wounds should be removed in a proper surgical unit under aseptic conditions with full protection against respiratory contamination and with provisions such that adequate surgical care can be complete. Even in the case of lacerated wounds it is better to make x-ray search for foreign bodies and leave the dressings intact, if too long an interval has elapsed for safe surgical intervention, until indications arise for their removal. In any case, treat the patient in a logical conservative manner to bring him through the critical period alive, leaving well enough alone. See to it that the blood volume is kept up, that unavoidable losses of blood plasma or cells are replaced, prevent or treat shock and promptly administer adequate chemotherapy. Keep an accurate record of the fluid intake and output and adjust the intake of fluid accordingly.

SUMMARY

1 The series of compression dressings offered makes possible adequate treatment of wounds, including the extensive surface wounds of burns and frost bite.

2 Three of the compression dressings are packaged with maximum compression for economy of space in shipment in the war effort and in carrying by personnel and to permit hospitals generally to store easily an adequate supply of sterile compression dressings for instant use in mass disasters.

3 The sterile ready-to-go compression dressings are devised to simplify the dressing of severe wounds so that the briefly trained person may become proficient in their application.

4 The oval pads of the individual dressings are designed to have sufficient firmness to collapse injured vessels and stop hemorrhage but to have ample resilience to permit circulation beyond the wound and to the tissue of the wound through the uninjured blood vessels, thus obviating the use of the tourniquet with its hazards.

5 The two new type dressings have a dual purpose, in that they may serve as thick spongelike pads for quick control of external hemorrhage or, by unfolding, may become wide coverage compression dressings.

6 The economy and saving of strategic materials is apparent.

Hospital care and treatment are today superior, generally, however, the critical period from the time of injury to the time of admission to the hospital offers room for improvement. This has been an effort in that direction.

A WORKING CLASSIFICATION OF THE CAUSES OF ABORTION

SAMUEL R. MEAKER, M.D.

BOSTON

The traditional method of classifying the causes of spontaneous abortion divides them into two major groups: fetal and maternal, each of which is again divided into numerous subgroups more or less ill defined. As a practical basis for diagnosis and treatment such an analysis tends to be confusing rather than helpful.

Every accomplished abortion includes three events: death of the embryo, separation of the ovum from its attachments and expulsive uterine contractions. Any one of these may be the primary event in a given case followed sooner or later by the other two. Thus abortion can be induced by killing the ovum with x-rays by dislodging it with the curet or by provoking effective uterine contractions with bougies. In the same way spontaneous abortions are initiated by accidents of three general types. A consideration of the causes from this point of view clarifies certain aspects of the problem of clinical management.

DEATH OF THE OVUM

In some cases of abortion the embryo dies days or even weeks before there is any evidence of ovular detachment in the form of bleeding or of expulsive uterine contractions in the form of cramps. In others the embryo already moribund dies after some slight appearance of bleeding or cramps but before these symptoms are well established. Such cases are of two sorts. In the first the trouble is hereditary, present from the moment of conception. Faults inherent in the germ plasma may produce anatomic defects, more often they lead simply to a state of insufficient vitality. In the second sort of case the trouble is environmental. A normal ovum succumbs after nidation either because of malnutrition from poor implantation or less often as a result of acute or chronic disease in the mother.

To speak first of the last mentioned item, situations in which maternal ill health kills a normal embryo in the uterus offer good examples of primary ovular death. In practice they are relatively uncommon, indeed, it is surprising how sick a woman can be without interruption of her pregnancy. Chemical poisoning, notably by lead and toxemia from local infection predispose to abortion, as do also thyroid disorders and diabetes. Malnutrition and avitaminosis appear to have the same effect though less than one might expect. There is a high incidence of abortion in febrile diseases such as scarlet fever, malaria and pneumonia, and while in some of these cases the primary event is uterine contractions provoked by high temperature or anoxemia more often the embryo dies first. On the other hand maternal syphilis, for all its disastrous consequences in the second half of pregnancy, is relatively harmless to the ovum during the early months.

Mall¹ and others have found that upward of 50 per cent of aborted embryos are pathologic. In Mall's opinion these malformations without exception are produced by environmental factors, chiefly by abnormalities of the uterine mucosa which interfere with nidation.

Read before the New England Obstetrical and Gynecological Society in Boston Dec 2, 1942.
From the Department of Gynecology of the Boston University School of Medicine and the Gynecologic Service of the Massachusetts Memorial Hospitals.

2 Hertig A T and Edmonds H W. Genesis of Hydatidiform Mole. *Arch Path* 30 260 (July) 1940.

tion, prevent regular growth of the trophoblast and thus affect the nutrition of the embryo. He states categorically "It is perfectly clear that monsters are not due to germinal or hereditary causes."

There is now, however, a considerable body of evidence to show that defects inherent in the germ plasma can and do cause weakness in the embryo if not actual malformations. Lethal factors in heredity are well known in lower animals. Something closely analogous has been demonstrated in human beings by Levine and his co-workers,³ who find that an Rh negative pregnant woman with an Rh husband may produce, as a result of immunization with the Rh fetal blood anti Rh agglutinins which can penetrate the placenta and hemolyze the blood of the fetus. The type of embryonal weakness most often encountered in practice is due to relative infertility of the spermatozoon or of the ovum, this being caused in turn by constitutional faults in one or both parents such as endocrine disturbances, chronic intoxications, debilitating diseases and poor hygiene. When disorders of this sort are severe they prevent conception, when present in milder degree they deprive the fertilized ovum of that vital energy necessary to carry it through pregnancy. The foregoing facts and others well supported by clinical and laboratory observations have led some workers to ascribe the majority of primary ovular deaths to preconceptional rather than postconceptional influences.

The literature of the past few years contains numerous papers⁴ reporting 80 per cent or thereabouts of successes in the progesterone treatment of both threatened and habitual abortion. The fact that a majority of pregnancies in which abortion is threatened can thus be carried to term, with the birth of normal babies is proof positive that the embryos are not inherently defective. It likewise sustains the views of Mall for the protective action of progesterone on the decidua would operate specifically to prevent the pathologic sequence of events envisaged by him. Equally definite conclusions about the ovum cannot be drawn from the reports on habitual abortion, since that diagnosis is often little more than presumptive. No doubt the administration of progesterone from the beginning of pregnancy can act prophylactically in the same way as it does therapeutically after a threat of trouble has appeared. When constitutional treatment of one or both partners is carried out before the start of pregnancy it may be assumed that increased fertility in the parents results in the survival of a certain number of embryos which otherwise would not have had enough vitality to complete their intrauterine development.

SEPARATION OF THE OVUM

The commonest initial event in spontaneous abortions is some degree of ovular separation. Bleeding was noticed before cramps in more than 80 per cent of my cases. Usually the first separation is not extensive, with proper treatment, or even without, healing may occur so that the pregnancy continues uneventfully. Under less favorable conditions further detachment takes place, the embryo weakens and dies, contractions supervene and abortion becomes inevitable.

There is probably no agent short of instrumental intervention which will bring about the detachment of a normal ovum properly implanted in a normal uterus. Healthy fruit does not fall from the tree until it is ripe.

³ Levine, Philip, Burnham, I. M., Katzin, E. M. and Vogel, Peter. The Role of Immunization in the Pathogenesis of Erythroblastosis Fetalis. *Am. J. Obst. & Gynec.* 42: 925 (Dec.) 1941.

⁴ Lotz, Jacob, Parker, Elizabeth and Kaufman, M. S. Treatment of Recurrent and Threatened Abortion. Report of Two Hundred and Twenty Six Cases. *J. Clin. Endocrinol.* 1: 835 (Oct.) 1941.

Primary separation of an ovum before the death of the embryo or the onset of expulsive contractions indicates therefore some defect in its attachments, either in the decidua or in the trophoblast.

The formation and the maintenance of a normal decidua depends on two factors: adequate endocrine stimulation and a healthy endometrium capable of responding. As Browne and his associates⁵ point out, between the twentieth and thirtieth days of most pregnancies there occurs a transfer from the corpus luteum to the placenta of the function of producing progesterone essential to the integrity of the decidua. If at this critical time or at any other the secretion of progesterone is insufficient (an event often evidenced by a fall in the excretion of pregnandiol), the result is regression of the decidua, disruption of its tissues by internal hemorrhages and separation of villi. A point often overlooked by clinicians is the role of estrogen of which an adequate production is necessary to prepare the endometrium pregnant or nonpregnant, for the action of progesterone.

Less frequent as a cause of poor decidua formation is inability of the endometrium to respond to physiologic stimulation. An important item in this category is uterine hypoplasia which would figure more largely than it does in the causation of abortion were it not that the accompanying hypoplasia of the ovaries makes conceptions few and far between. Inflammatory conditions likewise are more apt to produce sterility than abortion. The older literature has much to say about 'decidual endometritis'. This term usually represents a pathologic misconception interpreting as inflammation the dissolution and the infiltration with leukocytes, which are nothing more than a phase of the regression that follows withdrawal of progesterone. Nevertheless infections of the decidua, the placenta and the embryo itself do occur, either through the blood stream or by invasion from the vagina. The hyperplastic endometrium, an end result of more or less prolonged estrogen-progesterone imbalance, can rarely prepare itself for the implantation of an ovum. The same is true of the endometrium of the subinvolved uterus. This fact may sometimes account for a series of very early abortions, perhaps not recognized as such.

Defects in the trophoblast naturally predispose to ovular separation. Mall reports that the study of comparatively normal embryos often shows that the membranes are decidedly pathologic, the villi being deformed, diseased, atrophic or hypotrophic. Here again, as in the matter of ovular death, it is a question whether the disorder is primarily an imperfection inherent in the ovum or poor nutrition from faulty implantation. The theory has been advanced that the type of placental infarction seen in chronic nephritis may have its origin in disease of the young blood vessels of the chorion.

EXPULSIVE UTERINE CONTRACTIONS

In a minority of cases the threat of abortion is first announced by symptoms of uterine contraction. These commonly start as low backache with dull pain and a sense of weight in the pelvis, if the process is not checked, they soon develop into rhythmic cramps of increasing severity. Cramps without bleeding or followed by a show of bright blood are consistent with the possibility that the ovum is still normal. But when pains have been preceded by days of spotting or brown-

⁵ Browne, J. S. L., Henry, J. S. and Venning, E. H. The Significance of Endocrine Assays in Threatened and Habitual Abortion. *Am. J. Obst. & Gynec.* 75: 927 (Dec.) 1939.

symptoms and the combined thiamine suggests that the latter may be in a form unavailable to the body. The source of the thiamine in the feces remained to be explained.

Two possibilities to be considered were (1) that intestinal bacteria were manufacturing thiamine, a phenomenon that is known to occur in the rat under certain conditions and in the rumen of certain ruminant animals, (2) that the stores of thiamine in the body had not been completely exhausted and that the fecal thiamine represented an excretion into the intestine. The latter alternative seemed rather unlikely in view of the fact that urinary thiamine excretion had for many months remained at extremely minute levels. The possibility of thiamine excretion into the intestine was tested by administering 50 mg. of thiamine intravenously to 1 subject daily for one week in order to find out whether this was followed by an increased thiamine content of the stools. A negative result was obtained.

In order to obtain direct evidence for the production of thiamine by the intestinal bacteria one of the symptom-free subjects (G. B.) was given succinylsulfathiazole by mouth 1.5 Gm. every four hours for one week. The feces of this subject showed a prompt reduction in free thiamine from the previous values of 37 and 52 micrograms per day to zero within a week, and reappearing a few days after the drug was discontinued. Conceivably this negative result may have been due to direct destruction of thiamine by succinylsulfathiazole or to some interfering effect of the drug on the thiamine determination. Both these possibilities have been explored and ruled out. It is thus clear that the thiamine in the feces had its origin in the intestinal bacteria.

It is conceivable that the fecal thiamine was formed only by bacteria present in the large intestine, a site from which absorption of thiamine is perhaps impossible.

TABLE 2—Urinary Excretion of Thiamine Following Administration of Thiamine by Enema
(Micrograms in twelve hour specimen)

Subject	Before Thiamine Enema	After Two Thiamine Enemas
A	160	1,615
B	162	5,200

If this were the case, the presence of fecal thiamine would not explain the protection from the deficiency which these 4 subjects exhibited. In order to test this possibility, retention enemas containing 50 mg. of thiamine were given to 2 persons on successive days. Twelve hour collections of urine were made before this regimen was started (control period) and on the day the second enema was given. The results (shown in table 2) indicate a pronounced rise in urinary thiamine as the result of the thiamine enemas and provide ample proof that the large intestine can absorb thiamine.

It is not possible to state at the present time that thiamine requirements can be sustained for an indefinite length of time by such thiamine as is formed by intestinal bacteria. It may be that minute amounts of oral thiamine are needed for the growth of the bacteria which synthesize thiamine. The nature of the organisms which synthesize thiamine and the relation of diet to such bacterial synthesis are now under investigation.

The demonstration that intestinal bacteria can synthesize thiamine carries interesting implications for human nutrition. This phenomenon may explain the discrepancies in thiamine requirements found by differ-

ent observers. Since it is likely that the biosynthesis of thiamine is greatly affected by diet, as is known to be the case in animals, it follows that we must think in terms of requirements on particular diets rather than of requirements in general. It is quite possible that dietary factors other than the thiamine content may explain in part some of the paradoxes in the incidence of beriberi. The possibility of controlling thiamine deficiency by means other than thiamine administration remains to be explored. Finally, we may point out that the inhibition of the biosynthesis of thiamine by a sulfonamide drug has an important clinical implication for the physician who uses these drugs.

III CIRCULATION IN THE SKIN IN THE SHOCK SYNDROME

COMPARISON OF SIMPLE PROGNOSTIC FEATURES OF CLINICAL VALUE

JOSEPH R. DiPALMA, M.D.

BROOKLYN

"Early diagnosis and early adequate treatment" is a maxim which applies with particular emphasis to the shock syndrome. If impending shock could be suspected and treated effectively before changes in blood pressure and pulse sound the clarion call of approaching death, lives could be saved. Indeed it is even maintained by some observers that when the blood pressure falls and is maintained for an appreciable time below the so-called "critical level" and pulse changes are pronounced, a stage of shock has been attained which is frequently irreversible.¹ Hence the need for simple clinical methods which provide a means of diagnosing impending shock at the earliest possible moment. To accomplish this many attempts have been made, to date not one remains so effective as a serial follow-up of blood pressure and pulse. Among the promising are studies of blood concentration. Unquestionably they are of value in the shock arising from burns. They are not so satisfactory when applied to other types of the shock syndrome.²

My purpose in this investigation was comprehensive. It was to establish a physiologic and clinical basis for evaluation of certain features of shock states and to show that a few simple tests of the circulation in the skin are of diagnostic and prognostic importance in various types of the shock syndrome which are commonly encountered. The use of two recently developed methods of studying quantitatively the responses of the smaller blood vessels of the skin have made this possible.³ The first method measures two aspects of the hyperemic response (vasodilatation) consequent to a standardized period of local ischemia. First is the minimum time required to elicit a given degree of reactive hyperemia. The second is to measure the clearing time for this

Mrs. Blanche V. Richard rendered valuable technical assistance. This investigation has been aided by a grant from the Josiah Macy Jr. Foundation. From the Department of Medicine, Long Island College of Medicine, Kings County Hospital Division. Dr. Walter B. Cannon and Dr. S. R. M. Reynolds read and criticized the manuscript of this paper for which the author is grateful. 1. Cannon, W. B., and Cottell, M. K. Studies in Experimental Traumatic Shock. V. The Critical Level in a Falling Blood Pressure Arch. Surg. 4: 500 (March) 1922. Scull, C. W., and Kimball, J. Physiological and Clinical Basis for Treatment of Shock. Clin. 1: 43 (June) 1941. response. This it has been shown is an indication of the rate of blood flow in the skin. The second method measures the sensitivity of the small dermal vessels to give the so-called white reaction to graded mechanical stimulation (vasoconstriction).

PHYSIOLOGIC CONSIDERATIONS

Except for Grant, who has stressed the importance of clinical observation of the skin in shock, most observers dismiss the skin with the brief comment that it is pale, sometimes ashen in color, cold and sweaty.⁴ Little of a factual nature is therefore known.

Perhaps the best way to approach the problem is to state the commonly accepted view of the pathogenesis of the circulatory failure in the initial stage of the shock syndrome. This may be regarded as three definite but merging phases:

1. Reduction in effective circulating blood volume resulting in diminished cardiac output and diminished venous return. (The cause and mechanism do not concern us here but naturally may include trauma, hemorrhage, massive infection, burns, intestinal perforation or cardiac shock.)

2. Blood pressure maintained by vasocompensatory mechanisms. Pulse may or may not be altered.

3. Result is slowing of the peripheral blood flow. This is demonstrated in the skin by coldness of the extremities, cyanosis of the nail beds and sometimes actual stagnation of the blood in the small blood vessels.

It follows therefore that closer observation of the circulation of the skin by the use of certain objective tests of the skin circulation, to be described later, will yield important clues of impending shock before it is heralded by a fall in blood pressure or changes in pulse rate. While slowing of the peripheral blood can exist without the patient being in shock (as for example in cardiac failure, myxedema, peripheral vascular disease or in debility) it must be emphasized that the shock syndrome cannot exist in the presence of an adequate peripheral circulation. This truism has been given the attention it deserves in Harkins's recent review.⁶ In summarizing the results of numerous investigators who universally found slowing of the peripheral circulation in the early stages of the shock syndrome, he says "All these writers obtained confirmatory results and it seems to be without question that a decrease in blood flow is one of the prime factors in shock. So important and progressive is it that one might almost say that to diagnose shock a lancet to cut the ear or finger and determine the blood flow would prove almost as useful as all the sphygmomanometers ever made. If one were to select a single determination to follow the course of shock, an observation of the peripheral blood flow might be the best to choose."

To test the foregoing hypothesis the following observations were made:

METHODS AND PROCEDURES

No attempt was made to study just one type of shock. Rather, all patients in whom the faintest possibility of shock existed were seen as early as possible after they were admitted.⁷ The following standard procedure was

followed with each patient. First, a careful but brief clinical history was secured to establish an etiologic factor. In the physical examination which followed and usually done at the same time as the history, particular attention was directed to the following details. The patient was stripped and remained exposed to the room air. At this point the importance of examining the patient as a whole cannot be too strongly stressed. The skin was examined with the aid of a light of a 60 watt daylight mixed electric bulb.

Blanching Test.—First a rough estimate of the amount of blood present in the skin areas in the trunk, extremities and face was made. This was done by simply pressing the forefinger forcibly into the skin and observing the blanched area for color contrast with the surrounding skin. Naturally, it follows that if the skin can be blanched at all by pressure some blood must be present in it and the greater the color contrast with the unblanched skin the greater must be the amount of blood originally present. The rate of fill-in of the blanched areas also permits a rough though very unreliable, estimate of blood flow.

Temperature of the Skin.—Since the rate of blood flow determines the temperature of the skin, perceptible cooling of the skin, especially of the extremities, is an important indication of slowing the peripheral blood flow. It is not advisable to use instruments to do this because they are cumbersome, are not always available and the exact skin temperature actually means nothing in itself. What is important is to determine if there are any gross differences between the temperature of the skin of the trunk and the skin of the extremities. This can best be done by gentle palpation with the back of the digits of the hand. It is surprising what fine temperature gradation can be detected in this manner. Again it must be stressed that to do this properly the patient must be naked and exposed to room air for at least ten minutes and preferably for a longer period of time. To attempt to palpate skin temperature while the patient is covered by a blanket is ridiculous, and an extremity which has been in close proximity to a warm body will be warm because of direct transference of heat.

In this study, therefore, careful attention was directed to notation of unusual cooling of the skin of the hands and feet as compared to the temperature of the skin of the trunk.

Color of the Skin.—The color of the skin admirably reflects changes in the rate of peripheral blood flow. The best places to observe are the nail beds of the hands and feet, the lips and the cheeks. The observer by himself can become competent in visual judgment of the changes in skin color which are dependent on the amount and state of oxygenation of the hemoglobin present in the blood vessels of the skin in the following manner. Apply a blood pressure cuff to a suitable normal arm held at heart level and rapidly inflate the cuff to a pressure above the systolic level of the subject. Note carefully the skin color changes which attend the complete circulatory stasis. In about one minute the skin of the arm and forearm will become slightly pale and ashen in color, the nail beds very cyanotic. This limb now represents the changes in skin color which are encountered in the average case of shock in which there has been no blood loss. The arterial color which replaces the cyanosis on release of the pressure in the cuff serves to emphasize the type of skin color with excellent circulation. Now if the experiment is

⁷ Patients in this study included those in both the open and closed wards of medicine and surgery at Kings County Hospital. The majority of the staff both doctor and nurse gave an untiring cooperation.

repeated, this time the limb held high and the blood drained out of it before inflation of the cuff, the type of skin color changes encountered most commonly in hemorrhagic shock may be observed. In this case extreme pallor of the skin will be noted. Cyanosis can be detected only in the nail beds. Finally, if the experiment is repeated once more with the limb held dependent and blood allowed to collect in it, the skin color changes most frequent in medical types of shock such as that due to massive infection and shock of cardiac origin may be studied. In this case, the limb is plethoric and the color changes are more striking than in the foregoing instances. The bright red arterial blood color first changes to a duller shade of red, perhaps best described as brick red then purplish and finally deeply cyanotic. Thus it should be realized that a brick red skin color of the palm may denote considerable slowing of peripheral blood flow in a patient with a reason for going into shock. If deep cyanosis is waited for, many cases of impending shock may be missed.

Fig. 1—The ease with which the reactive hyperemia ring test is done clinically is illustrated. A weighted rubber ring is applied to the skin of the forearm for a period of seconds measured by the stopclock. By trial and error on different areas a threshold hyperemic response is determined. Note that no additional pressure is put on the weight. The forefinger merely balances it. The length of time required for the threshold response to fade is known as the clearing time and is related to rate of blood flow in the skin. In this instance two weights are used simultaneously to speed up the determination.

The Tache Response—One other clinical method of detecting slowing of blood flow in the skin has been found occasionally useful. This consists in stroking the skin rather forcibly with a blunt instrument such as the end of a ruler or the cap of a fountain pen. This response, best described by Lewis, in a normal skin consists in the appearance in a few seconds of a red line along the exact path of the stroking instrument. Surrounding the red line is an area of pallor and beyond this an arteriolar flare.⁸ Our procedure for the shock patient was to stroke simultaneously the skin of the chest in the area just above the breast and the skin of the forearm. Three things were watched for: (1) the length of time required for the red line to appear, (2) whether or not there was a delay in the appearance of the red reaction on the forearm as compared to the chest and (3) the color of the blood which composed the red line. No attention was paid to the presence or

absence of the surrounding pallor and flare, as this was found to be extremely variable.

The following conditions denote slowing of the peripheral blood flow: delay in the appearance of the red line beyond five seconds, and especially delay in the appearance of the red line on the forearm as compared to that on the chest. The color of the red line should be bright red. Altered shades of red, varying from brick red to a purplish red and even a deep cyanotic color, denote respectively a more severe degree of slowing of peripheral blood flow.

These four simple clinical tests of the circulation in the skin, while they are of inestimable value in the proper detection and judgment of the severity of the shock syndrome, still leave much to be desired. They are purely of a qualitative and subjective nature and require much experience to be interpreted properly. Moreover, they do not take into account environmental and seasonal factors, which are known to affect profoundly the circulation of the skin.⁹ The test to be described obviates these difficulties.

Reactive Hyperemia Ring Test—It has been found that the disappearance or clearing time of a standardized reactive hyperemia response produced by local ischemia of the skin is related to the rate of blood flow. Proof of this fact and, in addition, a description of the method, physiologic, seasonal, and aging variables, and its application to the clinical evaluation of peripheral vascular disease have been dealt with before in detail.¹⁰ As regards the method of its determination, suffice it to say here that it depends on the application of a weighted rubber ring (weight loading 100 Gm per square centimeter) to the skin of the flexor surface of the forearm. A stopwatch or a suitable clock is required to time the period of ischemia (application of the weight) and clearing time of the response after removal of the weight. Figure 1 shows the ease with which the test is done clinically. The minimal length of time, expressed in seconds, required to elicit hyperemic rings of uniform coloration, uniform width and with discrete edges is noted as the stimulus time or threshold for a response. The length of time required for the hyperemic rings to fade completely is noted as the clearing time. To establish a base line of seasonal and environmental factors a control reactive hyperemia ring test was done on the observer himself or a suitable normal patient in the same room as the shock patient.

Capillary Sensitivity—In this investigation one other test was done which, although not clinically applicable because of the complexity of the apparatus and the time involved, supplied important information concerning the reactivity of the smallest blood vessels of the skin. A strength-duration or excitation curve was determined by using a mechanical device capable of varying both the speed and the intensity of application of a stroker along the skin. This was done by finding the least weight in grams at each of five critical speeds of the stroker which produced a limited degree of vasodilatation against a background of vasoconstriction. The curve thus obtained was quantitated by means of the

formula recommended by Lassalle where excitability or E , is equal to $\frac{1}{\text{Rheobase}^2 \times \text{Chronaxie}}$. The reciprocal is used so that a low coefficient signifies low excitability a high coefficient a high degree excitability. Figure 2 illustrates three curves and the coefficient derived from each curve in a patient in shock from massive infection. A full discussion of this method is given elsewhere.¹¹ The significance of this test is this. Since normal data have already been secured for this response, comparison can be made with the results obtained in the shock syndrome. Moreover correlation can be made in the various types of the shock syndrome and in different stages with the degree of clinically observed and objectively studied alterations in rate of peripheral blood flow. This will be brought out in more detail later.

RESULTS

Forty-nine cases of surgical and medical shock of various degrees of severity have been closely followed. Eleven additional cases of suspected shock which later proved to have different disease syndromes were also studied. In the interest of brevity, 25 of these cases have been selected as a representative sample and summarized in detail in the accompanying table.

Clinical Evaluation—Review of the results in the table clearly demonstrates the value of the clinical examination of the skin in the shock syndrome. Particularly valuable is the estimation of the amount of blood present in the skin by means of the blanching test. It will be noted that the cases of hemorrhagic shock are the only ones which show definite diminution of blood in the skin. The cases of traumatic shock also often show some diminution of blood in the skin but in our experience never as much as the hemorrhagic ones. It should be pointed out here that mere notation that the skin is pale is not enough. Often it will be found that a patient who looks pale particularly under some lighting conditions actually has considerable blood in his skin when a critical attempt is made to determine this by means of the blanching test. The cases of medical shock such as massive infection and those of cardiac origin invariably show greatly increased amounts of blood in the skin, while those cases observed with ruptured peptic ulcer show diminution for only transitory periods and soon revert to normal filling of the skin even without treatment. Thus mere observation of the amount of blood in the skin gives an important clue as to the cause of the shock syndrome in puzzling cases. In this regard, particularly striking is the case of B S. Attention to the amount of blood in the skin would have led early to the correct diagnosis, and the life of the patient might have been saved. The clinician should have asked himself the question "Why is it that this patient who gives a story of blood loss and should have the appearance of hemorrhagic shock, actually has such a great amount of blood present in the skin?" Search at this time for a medical cause for the shock syndrome might have led to the finding of suggestive tenderness and spasticity of the lower abdomen.

As regards skin temperature and skin color, little need be said. The results are clearly summarized in the table. Suffice it to reiterate here that the mere finding of cold hands and cyanotic nail beds does not indicate at all that the shock syndrome is present. On

the other hand, they are very suggestive findings when they fit in with the history and other physical findings. Moreover, the insidious onset of coldness and altered skin color in a patient who was previously normal in this regard often presages the onset of the shock syndrome before evident blood pressure changes occur.

The tache response should be done in all cases. It is simple to do and gives information of slowing of blood flow in skin areas (forearm and chest) in which cooling and color changes are not so easy to pick up clinically. The table demonstrates the range of change which can be expected in shock cases.

Reactive Hyperemia Ring Test—This simple test proved more valuable than all others. It permitted objective determination of alterations in blood flow in the small blood vessels of the skin of the forearm. Reference to the table will bring out first the absence of variation of the readings in the cases of suspected shock from the normal controls. Of particular interest is the case of E H, who had a systolic blood pressure of about 70 mm of mercury for eight hours, yet by clinical signs and the reactive hyperemia ring test her peripheral blood flow was normal. The fact that she eventually attained normal blood pressure with just 1,000 cc of 5 per cent dextrose in isotonic solution of sodium chloride as therapy substantiated the impression that she was never actually in the shock syndrome.

Fig 2—Three strength duration curves on the same patient in shock from massive infection. An instrument capable of critically varying both the duration and the intensity of a stroke along the skin is used to determine these curves. They are quantified mathematically by use of the formula and graphic location of the rheobase and chronaxie as illustrated. The result is expressed as a coefficient reduced to the fourth power to give a simple digit as an idea of the excitability. A coefficient E or excitability above 0.5×10^{-4} indicates an increase in the sensitivity of the small dermal vessels and vice versa.

Three other cases of suspected shock are included in the table because they are particularly illustrative of the type of patient which offers trouble in the determination of the presence or absence of the shock syndrome. The first type is the patient who succumbs to a moderate or minimal amount of trauma. Blood pressure may or may not be lowered when the patient is first seen. Serial follow-up of skin circulatory changes should be done as well as frequent blood pressures and pulses. A change in the skin circulation may indicate the need for more intensive treatment before blood pressure or pulse changes occur. Conversely, a good skin circulation as in case S A¹ is a reassuring sign. The second type is a patient who is brought to the hospital with a history of falling suddenly on the street or down a flight of stairs and who incurs some degree of trauma. It is desired to know if the patient has had a cerebral vascular accident which preceded the fall or if the trauma incurred as a result of an accidental fall accounts for the superficial appearance of the shock syndrome. Case L S demonstrates the value of observation of skin circulatory changes under these conditions. The third type frequently seen in medical practice is the patient,

Type of Shock	Patient, Age, Sex	Orbital Diagnosis	Throat Diagnosis	Blood Pressure and Pulse			Clinically Detectable Skin Circulatory Changes on Admission			
				On admission	R P	P	Blanching Test	Skin Temperature	Skin Color	Tache Response
Septic shock	H 21 ♀	Spontaneous abortion with hemorrhage (?)	Acute multiple sclerosis	On admission Recovery	70/40 110/80	87 76	Normal amount of blood in skin	No abnormal cooling of extremities	Good arterial color	No delay good arterial color
	S A 1 ♀	Head trauma (?) fracture of pelvis fracture of right leg (?) traumatic shock (?)	Non-displaced fracture of pelvis	On admission Recovery	110/70 140/80	88 80	Normal amount of blood in skin	Slight cooling of fingers and toes	Good arterial color	Simultaneous appearance on arms and chest good arterial color
	H 11 ♀	Head trauma (?) internal injuries (?) traumatic shock?	Head injury (?) cerebral hemorrhage	On admission Deep shock	0/0 110/70	110 90	Supernormal amount of blood in skin	Hands and feet very warm	Bright arterial color	Immediate appearance supernormal responses cerebral tache?
	M 11 ♀	Coronary occlusion (?) cardiac shock (?)	Myocardial damage (?) clinical syndrome arteriosclerotic heart disease	On admission Deep shock Recovery	90/60 100/70 110/74	100 94 82	Supernormal amount of blood in skin	No abnormal cooling of extremities	Good arterial color	No delay, good arterial color
Traumatic shock	S A 2 ♂	Head injury (?) bilateral fractures	Fracture of right tibia and fibula and left tibia	On admission Deep shock Recovery	82/44 100/64 140/70	140 100 78	Fair amount of blood in skin hands plethoric	Pronounced cooling of hands and feet as compared to trunk	Cyanosis of hands and lips	Delayed but appear simultaneously on the arm and chest brick red
	M D 70 ♀	Compound fractures of both legs	Same	On admission Deep shock Recovery	0/20 60/2 140/80	100 96 81	Small amount of blood in skin	Extreme cooling of the hands and feet	Pronounced cyanosis of hands, feet, lips	Decidedly delayed, builds up slowly tache on arm comes up much later than on chest, cyanotic
	R A 61 ♂	Avulsion of left arm, multiple rib fractures	Same	On admission Deep shock Recovery	108/60 110/60 120/80	120 93 90	Fair amount of blood in skin	Hands and feet warmer than trunk (only skin on trunk is sweaty)	Moderate cyanosis of hands, feet and lips	Slight delay appears simultaneously on arm and chest brick red
	H S 21 ♂	Comminuted fracture of left tibia fracture of right tibia	Same plus head injury intracranial hemorrhage (?) hypertensive cardiovascular disease	On admission Deep shock Recovery	140/70 180/70 170/100	76 84 80	Supernormal amount of blood in the skin	Cold hands and feet as compared to the trunk	Cyanosis of nail beds and lips	Moderate delay in appearance of tache in the arms and chest fills in with a brick red color
	G A 69 ♂	Compound fracture of left tibia	Same	On admission Deep shock Recovery	90/70 100/40 110/60	84 90 88	Normal amount of blood in skin	Moderately cold hands and feet as compared to trunk	Slight bluish tinge of nail bed	No delay in tache response good arterial color
	J L 27 ♂	Multiple fractures of both upper extremities fracture of left tibia hematoma of abdominal wall internal injuries (?)	Same	On admission Deep shock Recovery	120/80 (leg) 140/100 (leg)	104 90 80	Fair amount of blood in skin	Moderately cold hands and feet as compared to trunk	Definite cyanosis of nail beds and lips	No delay in tache response brick red color
	P L 64 ♂	Comminuted fractures of both lower extremities	Same	On admission	50/0	110	Normal amount of blood in skin through out pooling in hands and dependent portions of body	Pronounced cooling of entire body	Deep cyanosis especially of hands, lips and feet	Impossible to elicit tache response even with most vigorous stroking except for faint cyanotic response on chest
	D B 45 ♂	Bleeding peptic ulcer	Same	On admission Deep shock Recovery	84/50 50/30 140/90	160 120 90	Very small amount of blood in skin	Pronounced cooling of hands and feet	Bluish tinge of nail beds and lips	No delay in tache response brick red
Hemorrhagic shock	H S 17 ♂	Bleeding peptic ulcer	Same	On admission Deep shock Recovery	90/60 80/50 140/82	140 130 96	Small amount of blood in the skin pale mucous membranes	Pronounced cooling of hands and feet as compared to the trunk	Definite cyanotic color of nail beds	Delayed pronounced delay in appearance on the arm cyanotic
	H K 59 ♂	Bleeding peptic ulcer	Same	On admission Deep shock Recovery	140/70 128/80 110/70	84 90 80	Fair amount of blood in skin	Moderate cooling of hands and feet as compared to the trunk	Nail beds reddish purple	No delay in tache brick red
	A S 08 ♂	Bleeding peptic ulcer	Same	On admission Deep shock Recovery	70/30 80/50 150/90	108 100 74	Bloodless skin	Pronounced cooling of hands and feet trunk warm	Cyanotic tinge of nail beds	Decidedly delayed good arterial color
	H R 36 ♂	Ruptured peptic ulcer	Same	On admission Deep shock Recovery	100/60 120/70 110/80	78 86 78	Normal amount of blood in the skin	Slight cooling of hands and feet	Nail beds reddish purple	Slight delay brick red
Ruptured viscous	H S 69 ♂	Ruptured peptic ulcer	Same	On admission Deep shock	0/0 70/30	9 120	Pooling of blood in palms of hands and in dependent portions of the body	Generalized cooling of the entire body	Deeply cyanotic almost black, especially palms of hands	Decidedly delayed comes up very slowly deeply cyanotic

Twenty-Three Cases

Objective Tests of Skin Circulatory Changes							Shock Therapy	Final Outcome	Comment
Reactive Hyperemia Ring Test *		Capillary Sensitivity Coefficient $\times 10^{-4}$							
	111	0 1	On Ad mission	Deep Shock	Recovery				
On admission	70	25	0 41		0 5	1 000 cc of dextrose and saline solution intravenously	Recovery	History of a fainting spell recent marriage bloody vaginal discharge and very low blood pressure which entitled admitting physician to make a diagnosis of abortion with hemorrhage development of definite neurologic signs 24 hours later brought out the true diagnosis	
Recovery	70	25							
Normal control	0	70							
On admission	20	25				1 000 cc of dextrose and saline solution intravenously	Recovery	Because patient was very restless sweating and asked continuously for water she was thought to be in impending shock	
Recovery	25	75							
Normal control	25	50							
On admission	15	50				Infusion started	Died in 8 hours	Flicked up on street automobile accident () initial blood pressure could not be obtained because of obesity of patient later on stertorous breathing and peripheral neurologic signs indicated hemiplegia which was immediate cause of death	
Deep shock	25	70							
Normal control	70	75							
On admission	0	40				Morphine	Recovery	Low blood pressure and precordial pain indicated a coronary occlusion excellent peripheral blood flow was against this diagnosis compare with cases of cardiac shock before	
Deep shock	35	45							
Recovery	25	40							
Normal control	25	25							
On admission	70	600	4 70	14 0	0 41	500 cc plasma 1 000 cc blood 2 000 cc dextrose and saline solution	Recovery (See graph)	Moderately severe traumatic shock seen early good response to therapy	
Deep shock	10	230							
Recovery	70	60							
Normal control	15	72							
On admission	170	900				500 cc plasma 1 000 cc blood, 2 000 cc dextrose and saline solution	Recovery (See graph)	Some degree of shock due to hemorrhage is possible amount of blood loss could not be estimated	
Deep shock	170	740							
Recovery	90	170							
Normal control	60	70							
On admission	150	900	0 65	5 30	0 71	1 000 cc blood 1 000 cc dextrose and saline solution	Died in 24 hours	Probably lost at least 500 cc of blood blood pressure did not fall until the very end but reactive hyperemia ring test revealed extreme slowing of peripheral blood flow note that capillary sensitivity coefficient rose to 70 just before death	
Deep shock	170	470							
Recovery	120	360							
Normal control	15	10							
On admission	70	210	0 18	0 70	0 17	1 000 cc blood 4 000 cc dextrose and saline solution	Died in 18 hours	Clinical picture indicated that immediate cause of death was head trauma note that clinical picture and tests denote the shock syndrome despite elevated blood pressure patient was known to be hypertensive	
Deep shock	105	600							
Recovery	55	200							
Normal control	70	72							
On admission	75	90	0 18	0 42	0 77	500 cc blood 2 000 cc dextrose and saline solution	Recovery	A mild case of traumatic shock with excellent response to therapy	
Deep shock	75	125							
Recovery	60	75							
Normal control	25	70							
On admission	105	155	0 46	0 80	0 77	1 000 cc blood 500 cc plasma 5 000 cc dextrose and saline solution	Recovery	Blood pressure could not be taken because of extensive trauma to extremities it was finally taken on the uninjured leg skin changes indicated early shock and the need for intensive therapy which was life saving	
Deep shock	90	210							
Recovery	60	115							
Normal control	70	27							
No response to local ischemia even after five minutes of application of the weighted ring							300 cc blood	Died in 30 minutes	Picked up on the street probably many hours after an automobile accident included to show terminal changes in the skin as a result of prolonged severe shock possibly some element of exposure to cold also present
On admission	180	165	0 61	9 40	0 77	2 500 cc blood 500 cc plasma 4 000 cc dextrose and saline solution	Died (See graph)	Despite adequate therapy bleeding from ulcer could not be stopped by conservative measures	
Deep shock	240	470

	T V 40 ♀	Rheumatic heart disease severe mitral stenosis multiple embolization (?) pulmonary infarct (?) auricular fibrillation	Same plus hemiplegia as a result of an embolus	On admission Deep shock	90/60 62 80/60 60	Supernormal amount of blood in the skin pooling in the hands	Pronounced cooling of the extremities	Trunk is of good color but extremities are cyanotic	Moderate delay in the arm as compared to the chest brick red

* TH = threshold C T = clearing time (in seconds)

usually known to have heart disease, who has sudden onset of precordial pain and the doctor notices that his blood pressure has fallen considerably. Here again, as in the case of A M, attention to the circulation of the skin is most helpful in diagnosis and prognosis.

Fig 3—A case of traumatic shock as a result of bilateral fractures of the legs. From above downward are pulse, blood pressure (shaded area), clearing time (triangles) and threshold (heavy dots) of the reactive hyperemia ring test. Solid black box is whole blood, box with P is plasma and box with S is saline solution, all in 500 cc amounts. Note the immediate fall of the clearing time (improved skin circulation) indicating the improvement in peripheral blood flow. Note also that this precedes the relatively slow rise in blood pressure and the great variability of the pulse.

The changes found in the reactive hyperemia ring test in the shock syndrome which results from trauma are shown in the table. It will be noted that in all cases

except one the threshold of the response is raised. This is not surprising, since it has been previously demonstrated that two factors known to exist in shock, anoxemia and acidosis, both tend to elevate the threshold. Also of great interest is the observation that hypercapnia will neutralize the effect of acidosis and anoxemia, and it is well known that acapnia is usually present in shock.¹² The changes in the clearing time of the response are even more striking. The rise in clearing time (i.e. decreased blood flow) ranges from three times to sixty times the control value dependent on the degree of slowing of peripheral blood, which obviously varies greatly in different degrees of shock and with seasonal and environmental conditions. From our experience we have set the arbitrary rule that a rise in clearing time of three times the normal control clearing time denotes a highly significant degree of slowing of skin circulation in the forearm.

The value of following the clinical course of a patient by means of the reactive hyperemia ring test is clearly demonstrated in the case of M D in the table and in figure 3. It will be noted that with therapy the blood pressure did not rise significantly. The pulse was extremely variable. The immediate and persistent fall in the clearing time, however, was a very hopeful sign. Thus, improvement in peripheral blood flow as indicated by the clearing time of the reactive hyperemia

ring test was the only objective finding on which a good prognosis could be based. Incidentally in this particular patient there was also clinical evidence of improvement in skin circulation by the tests that have been mentioned.

A low blood pressure maintained even for as long as eighteen hours as in this patient does not denote irreversible shock as long as the peripheral circulation remains adequate.

Case S A² in the table and in figure 4 illustrates another interesting point brought out by these studies. Peripheral blood flow as indicated by the clearing time of the reactive hyperemia ring test may remain relatively slow for a long period and even after the blood pressure has attained normal levels. This is interpreted as indicating that the patient is not yet out of danger despite an elevated blood pressure. Indeed, in this case (fig. 4) improvement in peripheral blood occurred at a time twenty-one hours after admission, when the blood pressure had diminished considerably.

In hemorrhagic shock the threshold is also elevated just as in traumatic shock. As a rule, however, there is not as pronounced an elevation of the clearing time as in other types of shock. This may indicate that peripheral slowing of blood flow is not so dominant a feature in hemorrhagic shock, especially in the early stages of the shock syndrome.

Case D B in the table and in figure 5 again demon- strates the value of peripheral blood flow studies by means of the clearing time of the reactive hyperemia

ring test. This patient, suffering from a severe bleed- ing peptic ulcer, had an initial blood loss of approxi- mately a quart of blood. When first seen his blood pressure was 84 systolic, 50 diastolic, and the pulse rate was 100. There was a moderate slowing of

Fig. 4—A case of traumatic shock as a result of multiple leg fractures. Symbols same as in figure 3 except for addition of the capillary sensitivity coefficient (top line squares). For complete discussion see text.

peripheral blood flow. Immediate restoration of blood volume with plasma and whole blood brought about quick and satisfactory improvement. Conservative therapy kept him well for seven days. At this time he had another copious hemorrhage which precipitated

much more severe shock. There was now a profound decline of blood pressure (fig. 5) and definite slowing of peripheral blood flow. With transfusion he again improved, his blood pressure attaining almost normal levels. His peripheral blood flow remained considerably slowed for forty-eight hours and then the clearing time began to creep slowly and perniciously upward despite the absence of change in the blood pressure. He died suddenly four days after his second large hemorrhage in spite of transfusions. Here again it must be mentioned that the clinically detectable changes in peripheral dermal blood flow correlated very well with the clearing time of the reactive hyperemia ring test. Thus in this case as in the other, serial observations on the rate of peripheral blood proved to be a better prognostic sign than alterations in blood pressure or pulse. Lest it be misconstrued that serial studies of blood pressure are of no value in shock let it be clearly emphasized here that this is not the case. The point which I wish to make is that both studies of blood pressure and peripheral blood flow must be done to evaluate properly the shock syndrome.

Fig. 5—A case of hemorrhagic shock as a result of a bleeding peptic ulcer. Symbols same as in figures 3 and 4. For full discussion see text.

The results obtained with the reactive hyperemia ring test in medical shock are summarized in the table and need not be dealt with at length.

Capillary Sensitivity—In this study it was desired to demonstrate that state of shock is associated with an altered reactivity of the smallest blood vessels of the skin. Former investigations in which the capillary excitability coefficient was determined on over 100 normal persons permits the statement that as a general rule the coefficient is practically never elevated above 0.5×10^{-1} .¹³ A rise in the coefficient as determined in this study indicates an increase in small dermal blood vessel reactivity. A fall signifies the opposite. The only diseases reported thus far in which the coefficient has been found to be definitely elevated are certain diseases of the central nervous system. Anoxemia, hypercapnia, local heat, stasis and certain steroids injected subcutaneously are also known to alter the coefficient of capillary sensitivity.¹⁴

When the results of the capillary sensitivity test are averaged for all types of shock presented, it is found that on admission the mean coefficient was 1.56×10^{-1} , during deep shock 4.66×10^{-1} and following recovery 0.31×10^{-1} . Thus it can be seen that even in this small series significant and striking changes in small dermal vessel reactivity are evident. Patient S. A. in the table and figure 4, with moderately severe traumatic shock, demonstrates these changes well. One hour after admission his coefficient was 4.90×10^{-1} . Despite therapy, a slight rise in blood pressure and considerable improvement in peripheral blood flow his coefficient rose to 14.00×10^{-1} in a period of six hours, demonstrating an extreme degree of increase in sensitivity of the small dermal blood vessels to mechanical stimulation. At this point the coefficient began to fall and in twenty-four hours had attained normal levels. This correlated with the clinical improvement, sustained blood pressure and more rapid peripheral blood flow.

In hemorrhagic shock there has not been observed such a large increase in small vessel sensitivity on admission. No significance is attached to this, as the average case of hemorrhagic shock when first seen is not very severe. However, should it become grave the small dermal vessel sensitivity increases, as demonstrated in the table. Patient D. B. (fig. 5) illustrates the ominous rise in small vessel sensitivity before death. It is worthy of note that the rise in the capillary excitability coefficient began forty-eight hours before the final failure of blood pressure and correlated in this case with the pernicious slowing of peripheral blood flow as shown by the lengthening clearing time of the reactive hyperemia ring test. The table illustrates the increase in small vessel sensitivity in deep shock as a result of other causes.

Thus it is evident that the state of shock is associated with an increased responsiveness of the small dermal blood vessels to mechanical stimulation as well as slowing of dermal blood flow. The question of whether or not this increase in small vessel sensitivity precedes slowing of dermal flow and actually is a causative factor (or vice versa) is an important one but unfortunately cannot be answered from the present data. The important point to establish at this time is that slowing of blood flow is not the sole factor in shock; changes in the small blood vessels also play an important role.

COMMENT

It is probably true that many expert clinicians have consciously or unconsciously learned to diagnose and evaluate the shock syndrome by accurate observation of the changes in temperature and color brought about by alterations in blood flow in the skin. However, it is not common knowledge and in general too little stress is laid on it. At the danger of tedious repetition it must be again pointed out that the shock syndrome cannot exist without slowing of peripheral blood flow; that the amount of filling of the skin with blood is important in the diagnosis of the type of shock; that only constant practice can make the physician expert in the clinical detection of slowing of blood flow in the skin and that a clinically useful and simple reactive hyperemia ring test is available for objectively determining changes in the rate of dermal blood flow. Moreover, alterations in dermal blood flow are often more diagnostic and prognostic than blood pressure and pulse changes.

¹³ DiPalma, J. R., and Foster, F. I. Sensitivity of the Smallest Cutaneous Blood Vessels. Quantitative Responses to Graded Mechanical Stimulation and to Local Ischemia in Arterial Hypertension, Arteriosclerosis and Certain Allied Disorders. *J. Clin. Investigation* 21: 675 (Nov.) 1942. Clin. Endocrinol.* 2: 228 (April) 1942. DiPalma, Reynolds and Foster.¹⁵

Finally, it must be recognized that slowing of blood flow in the skin while a very important and clinically useful method of diagnosing and following shock is not the sole factor present. Alterations in the responses of the small blood vessels are just as much a part of the picture. Unfortunately the latter cannot as yet be readily detected clinically and the exact relationship to slowing of the blood flow remains for future investigation.

Clinical Notes, Suggestions and New Instruments

POSTURE DURING EXAMINATION OF RAPID HEART

I. S. LUTON, M.D., St. Louis

During the summer of 1942 while examining a man with a rapid heart, I asked him to lean forward the better to appreciate the auscultatory findings. He responded by bending, to a 90 degree angle, when the rate abruptly slowed, apparently because of vagus influence. This was to me something new and was confirmed and since then has been verified in many tachycardias. This slowing occurred in most cases but not all and amounted to about one third of the previous rapid rate and required a full 90 degree angle for in some cases a bending to something less did not produce slowing. The most pronounced effect came in the first ten to twenty seconds when a gradual quickening ensued.

Many clinicians have wished to examine a rapid heart when slower and have relied on recumbency to secure this end. A forced expiration after a deep inspiration to slow the heart temporarily is recommended by the American Heart Association or recumbency and waiting for the nervousness to subside. There are murmurs due to a rapid heart action which disappear of course when slowed as do apical systolic grating murmurs in rapidly forcibly beating hearts, which simulate the murmur of mitral stenosis. From time to time in tachycardias difficulty is experienced in identifying the sounds, and pauses and murmurs of an organic nature are puzzling to time in the cardiac cycle. The apical systolic murmur is still a perplexing problem in a routine examination and several tests are used such as changes in posture and phase of respiration to help in separating significant from non-significant murmurs and it would seem that 90 degree bending might be used as an additional procedure especially in tachycardias—nervous thyrotoxicosis, flutter paroxysmal disorders and neuromuscular asthenia.

While this procedure has been used along with a great many others to influence an attack of paroxysmal tachycardia, a survey of some thirty or forty current textbooks on the practice of medicine, heart disease and physical diagnosis together with an equal number of reports here and especially in Britain of men writing on physical examinations of the heart did not disclose mention of the use of a 90 degree bend for the specific purpose of slowing the heart as an aid in its examination. This procedure is not to be confused with the one commonly used in having the patient lean forward to facilitate auscultation.

From time to time as opportunity presents itself an effort is being made to identify this procedure as an aid in specific heart abnormalities. It is hoped that others may try this along with other changes of posture phases of respiration and so on as an additional aid particularly in distinguishing normal from abnormal hearts.

BIATERAL CONGENITAL MUCOUS CYSTS IN THREE GENERATIONS

THREE GENERATIONS OF MUCOUS CYSTS OCCURRED WITH HARELIP AND CLEFT PALATE

CLAUDE LEROY STRAITH, M.D., D.D.S., DETROIT, AND
FREDERICK HENRY S. FATIO, MEDICAL CORPS,
ARMY OF THE UNITED STATES

It is not too unusual for a physician to have in his active years of practice a family with two or three generations of members with harelip cleft palate or both. Recently we have observed a family in which through three generations there was a tendency to bilateral harelips and also hypertrophy of mucous cysts in the lower lip of each individual with harelip or cleft palate. We believe this unusual distribution of congenital deformities in one family to be of interest to the profession.

In this family of thirteen persons there were in three generations six persons with bilateral harelips. Some of these patients had an associated cleft palate as might well be expected, but more interestingly each had a pair of hypertrophied mucous glands on the lower lip. These glands secrete a tenacious mucous material from two very prominent excretory ducts which open just above the mucocutaneous line of the lower lip. They are 1 cm. apart and are placed in the center of the lower lip. On the mucous membrane surface they appear to be blue and about the shape of an almond pit. In the adult they measure 2 by 0.5 cm. These glands have been described as mucocysts, retention cysts or congenital fistulas.

Fig. 1—Five members have had bilateral harelip cleft palate and mucous glands. The insets show evidence of these deformities in the first and second generations.

Truman W. Brophy¹ pictures these deformities in his textbook on oral surgery. He quoted Sir Arthur Keith's—belief that these cysts might be a reversion to a certain species of shark in which such glands occurred. In reviewing the literature and checking with two responsible sources we can find no such evidence in the Elasmobranchs. It is known that as certain amphibians assume the terrestrial life, lateral line organs sink beneath the skin and atrophy. This might be an analogue to this condition. Also in fishes the hyomandibular line forms two anterior pores in the lower lip posterior to the symphysis and may be a zoological ancestor to this deformity. In human embryology no clear explanation is to be found for the uniformity and size of these cysts. We do

¹ Brophy, Truman W. Cleft Lip and Palate Philadelphia P. Blakiston S. Son & Co. 1923, p. 66.

² Keith, Sir Arthur. Brit. M. J. 2, 363, 1909.

know that mucous cysts occur abundantly in this region and that hypertrophy of the lower lip occurs routinely when there is lack of pressure from opposing tissue, as in harelip. Also we have observed these glands and lips decrease in size after surgical repair of the harelip. We cannot, however, explain to our satisfaction the occurrence of two symmetrical glands when many other such glands are in the vicinity. The occurrence

Fig. 2—An example of bilateral harelip and mucous glands in the third generation of this family

must follow mendelian laws in these cases and the glands must have some analogue other than the numerous small mucous cysts found in this region.

In figure 3 we present as accurately as possible the family genetic history. The father had a double harelip, cleft palate and mucous cysts. The mother of the second generation had a congenital syphilitic perforation of the hard palate. This was untreated when her first two harelip children were born.

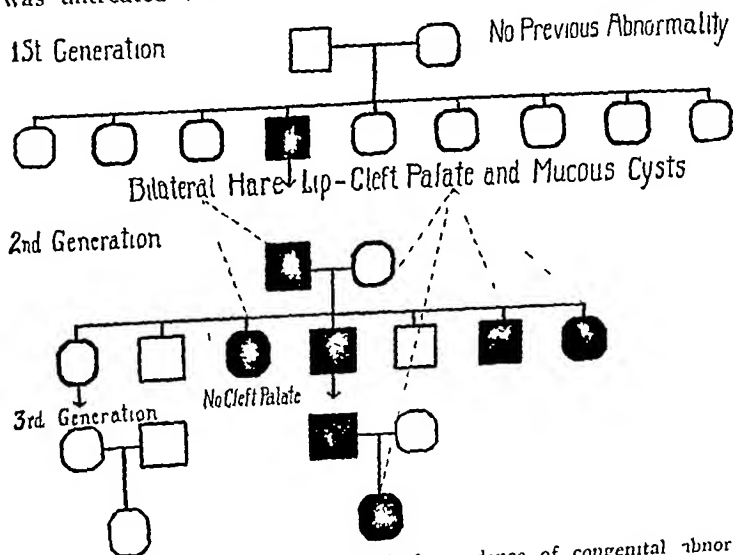

Fig. 3—Family history, showing high incidence of congenital abnormalities

This infection was then treated and her Wassermann reaction was negative when the next two harelip children arrived. None of these children have congenital syphilis today. The mother's sisters, however, are under treatment for congenital syphilitic lesions. We do not feel that this disease influenced the frequency of deformities in her offspring. This same mother's syphilitic palate lesion came on spontaneously and healed under antisyphilitic therapy.

In figure 1 some of the members of this unusual family are shown with their bilateral mucous glands of the lower lip.

Figure 2 is an example of double harelip and bilateral mucous glands before surgery.

We have found that simple excision of the gland and some tissue reduces the size of the lip and eradicates the glands. Of course no glandular tissue should be left for fear of recurrence.

CONCLUSION

We report three generations of a family, having six of thirteen members presenting bilateral hypertrophy of mucous cysts associated with cleft palate and harelip deformities. It would appear that in this family the genetic factor responsible for these glands is as dominant as is the harelip factor. Simple excision is the treatment of choice. (These cases are presented as we have not found three generations of bilateral mucous cysts described in the literature before, also because of the relative infrequency of the condition.)

THE TREATMENT OF CREEPING ERUPTION WITH SODIUM ANTIMONY BISCATECHOL (FUADIN)

DUDLEY C. SMITH, M.D., CHARLOTTESVILLE, VA.

Creeping eruption, or larva migrans, is a condition characterized by progressive, linear burrows caused by the larvae of a number of different parasites. The larvae of flies and intestinal parasites have been reported as causing this condition. The larvae are found most abundantly in warm, sandy soil. They penetrate into the epidermis and migrate slowly, causing intense subjective symptoms. The larvae do not penetrate deeper than the epidermis. The majority of cases in this country result from the larvae of the dog and cat hookworm. This abnormality is apparently most prevalent in the southeastern portion of the United States, especially Florida. There have been seen in this clinic 2 cases which were acquired on the beaches of Virginia.

The treatment usually recommended is freezing or cauterization of the skin at the site of the parasite. The parasite is usually present in the area around the advancing end of the burrow within a radius of 1 centimeter. Local treatment in this area is not uniformly successful in producing a cure. In cases presenting a large number of lesions this type of treatment has disadvantages.

Recently (Jan. 22, 1943) a 2½ year old boy was seen at the University of Virginia Hospital with a condition characteristic of creeping eruption. His history is as follows:

In the latter part of September 1942 the patient was living in New River, S. C. His mother first noticed the migrating linear eruption on the left foot. This started as a red spot and advanced in an irregular line. There was intense itching. Later a number of similar lesions developed in the perineal and perianal areas. The symptoms were so severe that the child had difficulty sleeping. A number of local applications failed to give symptomatic relief or improve the condition. No attempt was made to identify definitely the type of larva.

Because of the age of the patient and the location of the eruption, the usually recommended measures for local treatment presented difficulties. Sodium antimony bismatechol (Fuadin), used with success in other protozoal diseases, such as heart worm in dogs and Vincent's stomatitis, was therefore considered for treatment in this case. A 63 per cent solution was used, of which 2 cc solution was given intramuscularly and the home physician was to continue this dosage at daily intervals for five days, discontinue for one week and then give five more similar daily injections. The first injection was given on January 22. On February 24 Dr. J. F. Hubbard, the family physician, reported that the boy was started on 2 cc intramuscularly daily beginning January 23 and given five doses. After the lapse of a week the medication was started again with 2 cc intramuscularly daily for three doses. The eruption began to clear up after two or three doses of the first course.

From the Department of Dermatology and Syphilology, University of Virginia, Department of Medicine, W. E. and White, G. F. Creeping Eruption, Arch. Dermat. & Syph. 13: 137 (Feb.) 1926.

and was entirely gone by the time the fifth dose had been given. The second series was begun, but as the child seemed entirely well and was sleeping all night, which he had not done for a long time, the treatment was discontinued after the third injection of the second series, at his mother's request. There was no recurrence.

On February 15 the patient's mother stated: 'From the first injection of Furdim Bobby's eruption began to dry up, no more has appeared and he has had no bad reaction whatever.' On March 13 the boy was examined again. There were no gross or subjective evidences of larva migrans.

COMMENT

Search of the literature reveals no reference to the use of Furdim in the treatment of creeping eruption. Antimony (formula not mentioned) was used by Craston² without success. The improvement here reported was so prompt and permanent that this record is submitted with the hope that physicians in areas where the infestation is more prevalent will give this agent further trial.

The successful administration of treatments in a health resort depends to a considerable degree on the physical equipment available and the intelligent use of these facilities.

I GENERAL PLANS

The design for any institution depends first on the number of treatments to be given and, second, on whether or not the institution itself provides the entire care of the patient, including living accommodations and treatments. A system of multiple units is presented which can be applied in either the small or the large institution.

The buildings required for administration of treatments will differ somewhat with the type of water and nature of the service provided. Fundamentally, most institutions will utilize mineral waters or muds in some way. Most places are equipped to provide additional hydrotherapeutic treatments, various forms of packs and massage. In some places further specialization may include the use of waters for inhalations, the application of physical exercise as mechanotherapy and the utilization of light and electricity in various forms.

In planning a bathing establishment it is also necessary to determine, as already mentioned, whether it is to be an independent unit or part of a hotel or sanatorium. In the former, adequate space must be provided to allow for the proper rest period following the treatment. If the bathing unit is a part of the hotel, the rest period can be provided by returning the patients to their rooms. This will allow for more rapid turnover of bathing facilities and increase the number of daily treatments per unit to the maximum.

In the bathing establishment the control office provides for the collection of charges, the checking of valuables and the assignment of patients to the various treatment sections. In general, separate sections with duplicate equipment must be provided for men and women. In larger institutions several separate sections may be connected to a central lobby. These sections can be used for either men or women, depending on the requirements.

A Baths—Provision for bathing is usually made with individual tub units. In a very few resorts the treatments are given in a natural bathing pool. The most practical unit both for privacy and for efficiency consists of a tub room, connected with two rest rooms, all of which must be directly accessible from a hall or passageway. This provides for adequate rest space, service and privacy and allows for more frequent utilization of the technical equipment. The number of such units will depend on the volume of work. Figure 1 is a sketch showing an arrangement of a semiprivate bath and rest rooms.

In some places the strictly private room arrangement is in use. Here the patient has a tub and rest couch in the same room. This private room arrangement is an expensive installation in that it ties up the tub equipment during the entire rest period of the patient, and in general it provides no additional privacy. In some institutions the bathing section may be arranged in a series of treatment cubicles where the bath or other associated treatment is given. The patient is then sent to a general rest room in another corridor. Aside from the inconvenience of going from the treatment room to the rest room and the lack of privacy, this arrangement is particularly satisfactory where the demand for treatments is large.

In any case the particular plan selected will depend on the type of the clientele.

² Craston, F. C. Creeping Eruption at the Natal Coast. J. Trop. Med. 3: 374-375 (Dec.) 1934.
From the Medical Department of the Saratoga Spa.

B Hydrotherapy—A hydrotherapy department is usually separated from other treatment sections and should be complete in itself with hot room, steam room, electric cabinets, rubbing tables, douche stall with control table and resting facilities. In small installations the hot room and steam room may be omitted for lack of space.

Arrangement of the various units in this department for convenient and efficient operation is shown in figure 2. The technical details of these units will be considered in a later section.

C Packs—In many bathing establishments some form of pack is utilized as an adjunct to the bath or as a separate treatment. In smaller institutions packs may be prepared in the mineral bath tub. This arrangement generally is not satisfactory because it limits the use of the tub for baths and frequently proper facilities for preparing the pack cannot be provided. It is much better to have a hot pack department with cubicles adjacent to the bathing section and space for the proper equipment.

D Massage and Special Treatment—Provisions for massage may be arranged in a separate massage room in the bathing section or it may be given in the rest

rooms allowing for individualization and economy of operation in small departments. For practical use these cabins are large enough to accommodate one chair and are about the size of a telephone booth.

The wall cubicle allows the patient to sit at a small treatment table or sink, where provision is made for breathing the nebulized mineral waters either through the nose or mouth and where accessory apparatus is available for administering medicated oils in finely nebulized vapors.

E Mechanotherapy—Mechanotherapy rooms in general are large halls provided with varying apparatus to allow both for general and for local exercise. The apparatus may be either for active or for passive exercise. In the former the patient provides the motive power while with the passive group some source of power, either central or local, must be provided to operate the machines. If the problem is one of general exercise such as is associated with a reducing program, provision should be made for such types of apparatus as the electric horse or camel, stationary bicycle, rowing machine, chest weights and mechanical and vibratory massage. If the program of treatment is more particularly rehabilitation then it is necessary to have the types

of apparatus which will allow for the exercise of individual joints. A large series of the latter group have been worked out by Zander and can be applied to a wide range of conditions. Their use in this country today is extremely limited. Many physicians prefer to rely on a trained attendant rather than on the machine, which lacks adaptability. The requirements for a complete mechanotherapy unit are large from the standpoint of space and of mechanical equipment. These units are therefore

Fig. 1—A semiprivate bath arrangement

room itself if it is of sufficient size to accommodate a portable massage table. The first arrangement is satisfactory to the large majority of patients. A few may desire the greater privacy afforded by the second plan.

Additional treatment, such as the use of infra-red rays, ultraviolet radiation and various electrical treatments may be combined in a room similar to that used for massage. Such rooms should be in or near the bathing section as these treatments are frequently combined with the bath and carried out by the same attendant.

E Inhalations—The inhalation department is a separate division which can be located in a wing of the bath house or in a separate building. Provisions can be made for three units: first, a large room for group treatment, second, an individual cabin and third, a table unit in a wall cubicle.

In the group treatment room the atmosphere is saturated with the gases directly from over the mineral water springs or with the finely nebulized vapors of the mineral water. Here the physician has no opportunity of individualizing for his patients unless a series of rooms at different temperatures are provided.

In the individual cabin, mineral water vapors of various concentrations can be given at different tempera-

tures allowing for individualization and economy of operation in small departments. In many places, however, a limited number of exercise machines may be used to advantage in smaller space.

G Mud Baths and Packs—The administration of mud baths calls for elaborate equipment. The necessary means for supplying, storing, heating and preparing the mud for the bath, its transport to the tub and its disposal after use all call for special consideration and attention. For practical purposes mud baths should be considered only when adequate facilities and ample space can be made available. A separate building is most desirable. The bathing unit in this building must be larger than the three room unit described for mineral water baths, as two tubs must be provided: one for the mud bath with a tub adjacent for a cleansing bath following the mud treatment. Therefore the administration of mud baths should be attempted only after careful consideration of all the facilities required.

On the other hand, the use of mud for packs does not require so complete a layout. The pack may be a full body pack omitting the upper chest or it may be limited to local packs on an extremity, the liver region, spinal region and the like. Here the treatment unit can be made up of individual pack rooms or cubicles surrounding a central mud heating unit.

H Drink Halls—In practically all health resorts provision is made for the internal use of the mineral waters. The simplest arrangement, of course, is to have the patients go directly to the spring. In some places the mineral water is piped directly from the spring to a special section of the general bathing establishment. In other places a separate building or drink hall provides facilities where many patients can obtain the water as prescribed. Also, if possible, it is of value to have music or concerts during the day when the waters are usually taken. The extent of this phase of the work will depend on the number of patients coming to the health resort for treatment.

I Linen and Service Rooms—Because of the large quantities of sheets and towels required, an adequate supply can best be maintained if a laundry is run in connection with the institution. Each bathing wing or group of bath rooms should be provided with a linen room in which reserve sheets, towels and other materials used in the actual work of the wing may be stored. The service or linen rooms are usually connected by dumb-waiter with the basement through which the laundry and general service is operated.

J Attendants' Rooms—In planning a large bathing establishment it is of real importance to provide adequate facilities for the attendants where they may have locker space, shower baths and tables for eating lunch. It has been found that the provision of such space pays dividends in the better satisfaction of the staff and in removing all evidence of street clothing from the patient's vision.

K Swimming and Mineral Water Pools

In many health resorts, provision is made for the utilization of the natural water in swimming pools. These pools are generally provided in a separate building although in some places they may be a part of the treatment unit. The size of a swimming pool depends on the number of guests to be accommodated. General and technical descriptions for the proper arrangement operation and control of swimming pools are available.

In some places special treatment pools are provided in which the natural mineral water is used in exercise treatments either for the patient convalescent from poliomyelitis or for the patient with chronic arthritis. Here the size, shape and necessary provisions for construction have been outlined by Lowman.¹

II TECHNICAL EQUIPMENT

Spas are usually built around a mineral spring or group of springs that have some proved medicinal value for either internal or external use or for both. The first and most important consideration, therefore, in the establishment of a spa is the study of the mineral

water supply and the equipment necessary to conduct it to the place of utilization.

The first thing to determine is whether or not the supply is adequate and sufficiently uniform in flow and composition to warrant the contemplated development. Considerable time and expenditure of money may be involved in gaining such information. If the springs are shallow natural flowing springs both the flow and the mineralization may vary at different periods of the year. Therefore, frequent measurements of flow and partial chemical analyses should be made over several seasons to determine such facts. If the wells are artesian in nature and the flow is a natural one there is apt to be less variation but if pumping is required studies must be made to establish the rate that will assure a uniform mineralization. When it has been definitely established that the mineral water supply is satisfactory, methods of storage and distribution must be planned.

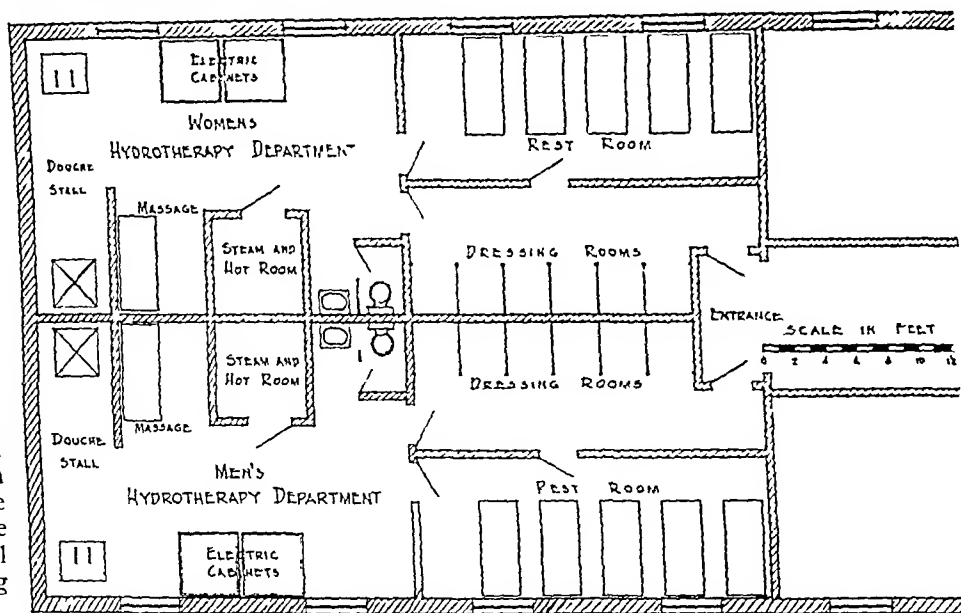

Fig 2—Arrangement of units in hydrotherapy department.

L Storage—Methods of storage are dependent entirely on the nature of the water, the extent of the supply and the volume demanded. The volume demand at some period may exceed the supply. In such cases larger storage may be required. No set rule can be made to apply to all waters with the exception that waters that come from the darkness should be kept in darkness.

Light affects all artesian waters in one way or another, such as the promotion of the growth of algae in open reservoirs or the precipitation of iron when exposed to the air.

Waters that contain no volatile gases or salts that would be precipitated may be stored in the covered concrete reservoirs of either a gravity or a pumping system.

Mineral waters containing either carbon dioxide or hydrogen sulfide gas should preferably be stored in closed systems under pressure and entirely free from contact with the air. Such storage will prevent the precipitation of iron and other minerals that are common constituents of gaseous waters. No method is known for the satisfactory storage of waters containing radon (radium emanation).

¹ Lowman C I, Reen Susan G, Aust Ruth and Paull Helen G. *Technique of Underwater Exercises*. Los Angeles: American Publications Inc. 1914.

Waters that flow from the ground at elevated temperatures need only be cooled before entering the bath tub or treatment room. This cooling can be accomplished by holding the water in storage for a definite time or as is done in some resorts by passing the water through radiators which furnish required heat purposes.

Water is stored under pressure proper control is installed so that the pumps work automatically either directly on the well or from pump chambers into which the spring water flows. If the waters are highly carbonated the system from the well to the storage tanks must be entirely closed and the water conducted through the distributing lines to the baths with the least possible agitation to prevent dislodging the gas. The water should be brought into the tub at or near the bottom through a fixture so designed that smooth flow and even distribution are accomplished.

B Metals Used for Storage and Distributing Systems—Special attention must be given to the type of metal used for the tubing of wells, tanks used for storage and the distributing lines. Waters that are alkaline in nature and are free from excess of carbon dioxide or hydrogen sulfide can be handled most economically using a good grade wrought or cast iron pipe. Steel pressure tanks that may or may not be coated on the interior with a protective plastic or rubber base paint.

Mineral waters containing large excesses of carbon dioxide or hydrogen sulfide are the most difficult to store and distribute. They are always very corrosive toward metals, particularly iron or steel and wherever these metals are used means must be taken to use protective coatings or to establish a chemical protection, the nature of which can be determined only through chemical study of the water. The basis of such treatment is the precipitation of an insoluble substance on the metal.

Pure copper and some of the copper alloys are the best metals to be used with the carbonated saline waters, in conjunction with steel pressure tanks that are either glass lined or protected with a suitable acid resistant paint. For conducting carbonated waters that are to be used internally, red brass pipe that has been tin coated is the most satisfactory equipment. Most mineral waters of the carbonated type have a very drastic initial action on pure copper, but after a short time a coating is formed on the metal that protects it from further attack.

Sulfur waters can be handled in copper alloy pipe or in wooden stave pipe. Iron pipe lasts but a short time with these waters.

Bath tub fixtures should be made, wherever possible of cast stainless steel. Nickel and chromium plated fixtures do not withstand the action of most mineral waters. They are affected by salt waters, alkaline waters, sulfur and carbonated waters.

C Heating of Mineral Waters—The heating of mineral waters is probably the most bothersome and expensive problem associated with spa operation. This problem is encountered in all types of waters except those that issue from the ground in the form of hot springs.

Waters that are brines containing as their main constituents sodium chloride or soluble salts of magnesium and calcium can be heated to sufficiently high tempera-

tures or the heat is in the ordinary heating equipment designed for fresh water with minimum difficulties caused by scaling or corrosion.

Waters containing large volumes of carbon dioxide gas along with the bicarbonates of the alkaline earths are the most difficult to handle. On heating carbonated waters large volumes of carbon dioxide gas are liberated and salts of lime, magnesia and iron are simultaneously precipitated coating tanks, pipe lines and fixtures with hard scale that reduces to a minimum the efficiency of heating units and in a very short time renders all small lines useless.

Much study has been given to the heating of these waters both here and abroad. In many places in Europe the water is heated to the required bathing temperature directly in the tub by a small radiator through which high temperature steam is passed. The radiator itself is supported on a swing joint so that when not in use as a bath heater it is swung up on the wall where it may either be turned off or used as a room heater. This method produces a fine bath with high carbonation but has two very objectionable features. First large volumes of carbon dioxide are liberated in the room where the patient is to be treated and the atmosphere becomes very dense with the gas making breathing difficult. Second the heater itself after short use becomes coated with scale that chips off when the steam is turned on for a succeeding bath. This is usually very objectionable to the patient. Instantaneous type of heating of the water as it enters the tub has been tried but without success. The gas is liberated from the water so rapidly that the finished bath is absolutely flat.

At Saratoga Spa a special pressure heating system has been designed and in use many years with highly satisfactory results. The heater tanks are kept under constant pressure and are designed so that the free gas forms a cushion at the top of the tanks. Heat is applied through a copper steam coil in the bottom of the tank and the temperature is thermostatically controlled at 135 to 140 F. It has been found that at higher temperatures excessive precipitation occurs and the iron in the water oxidizes very rapidly when the water is drawn in the tub. As the heating proceeds, some carbon dioxide is liberated and the excess pressure produced thereby is relieved through an automatic valve on top of the tank. The carbon dioxide thus bled off is trapped into a sewer line. The hot water saturated with carbon dioxide, is drawn directly into the bath tub and the preparation of the bath completed by adding cold, highly carbonated water directly from storage.

The scale formed in heating is trapped in the tank where it can easily be removed. The atmosphere of the bath room is nearly normal because of the elimination of the large volume of carbon dioxide gas at the heater tank.

D Boiler and Pumping Plant—A central boiler plant is desirable in all spas where the patronage is large. The source of heat may be derived from oil, coal or gas, depending on which is most economical. Wherever possible, oil or gas should be given first consideration because of the ease of automatic control, the absence of ash and smoke nuisance and the lower maintenance cost. If coal or coke is used, automatic stoking should be installed.

The boiler plant should be of much larger capacity than the usual plant where there is a steady steam load. Unusual and sudden steam demands are the rule at most spas at certain hours of the day and this demand must be met by providing liberal boiler capacity and steam reserve.

The spa buildings should be grouped conveniently around the boiler plant and connected with it by subways for carrying both steam and water lines, thus affording easy access for repairs.

Pumping equipment, whether steam or electric should be long stroke and slow moving so as to reduce the agitation of water to a minimum.

E Laundry Facilities—The linen demand for spa work is large, from four to eight pieces being required for each treatment. Since it is not always possible to provide adequate linen through an outside service, provision for a laundry building should be given thoughtful consideration. Such a building should be located near the boiler plant for easy steam supply and requires the installation of washers, air driers, centrifugal driers, ironers, necessary baskets and tables, and small trucks for collecting and delivering linen. Adequate space should be provided for the storage of linen and the various chemical supplies needed for operation.

F Bath House Fixtures and Equipment—Most spas provide, in addition to mineral water baths, adjunct treatments including mineral packs, mud packs, various types of douches and sprays, hot rooms, steam rooms and water rubs. The materials and design of equipment must be chosen with the same care as other mechanical equipment.

1 Bath Tubs—Bath tubs should be large enough to immerse a patient completely in a relaxed position. Usually the tub should be about 6 feet long by 24 inches deep by 24 inches wide, to meet this condition. These dimensions provide a tub that is suitable for the taller patients. A foot rest made of stainless steel or some resistant metal, provided with a base and four rubber suction cups, can be placed anywhere on the bottom of the tub by the attendant to suit the comfort of the shorter patient.

Tubs made of porcelain or iron coated with acid resistant enamel are most suitable. Other materials used for tubs include native mineral rock, wood, slate or concrete. Sometimes concrete is covered with a metal sheeting such as copper or aluminum. The latter has been used with sulfur waters.

2 Packs—Hot packs may be given either with mineral water or with fresh water. If fresh water is used, the autoclave type of pack heater is most convenient. The pack material is placed on shelves in the autoclave and steam is kept flowing through, so that the packs become wet and heated to the proper temperature.

If the packs are to be prepared from mineral water, a hot pack sink must be provided. This sink should be of porcelain or slate, so that it may be easily cleaned with acid. Hot mineral water is piped to it and a suitable wringer attached for wringing the packs.

Mud packs require much special equipment. There should be rooms with suitable couches on which the patient reclines during the application of the packs. These rooms must be provided with either a tub or a shower to cleanse the patient after the application of the packs. Resting facilities must also be provided. The

equipment for grinding, mixing and heating the mud should be installed in a separate room. Flowing steam is passed through the outside jacket, and either hand or motor operated paddles revolve to bring the mud to a uniform temperature. Grinding equipment is similar to that used for paint grinding and can be obtained from the same manufacturers.

3 Hydrotherapy—In considering the technical features of the hydrotherapy department the hot rooms should be large enough to accommodate several people reclining in chairs of the steamer type, covered with a sheet to protect the patient from burns. The source of heat can be steam radiation provided in the room itself or circulated conditioned air from a conditioning plant. Whatever the source of heat may be, when moisture is provided much lower temperatures can be used. The usual temperatures are between 140 and 160 F, depending on the amount of humidity present.

Steam rooms are usually small and are entirely of tile with a domed ceiling to prevent hot condensed water from dropping on the patient. The steam is introduced into the room through atomizing nozzles so as to produce a fog. Marble slabs are provided for the patient to sit or lie on during treatment.

Both hot and steam rooms should have windows so that the attendant can watch the patient.

Rubbing tables are constructed of marble on which sponge rubber mats are placed. Directly over the rubbing table a series of sprays are suspended which are controlled by a mixing valve. These sprays are used following the salt or soap rub or may be used on the patient while the attendant administers massage.

The douche equipment is located in a shower stall the walls of which are usually constructed of slate, marble or tile. The floor should be of tile and preferably of the nonslip type to avoid accidents.

At the extreme end of the stall a shower equipment is placed. This shower is provided with a rain douche applied from overhead, and needle sprays that impinge on the patient from four directions, covering every part of the body but the face. The temperature and pressure of the water are controlled by an attendant through a douche control table placed at the opposite end of the stall. This table is also equipped to administer the "Scotch," jet and fan douches.

III METHODS OF CLEANING AND SANITATION

Particular attention must be given to keeping any bathing or hydrotherapy department scrupulously clean and sanitary.

To carry out such a program the rooms, floors, walls and equipment should be constructed of materials such as tile, marble or porcelain that lend themselves to easy cleaning and sterilization.

All equipment that is used in conjunction with sulfur water or waters containing iron should be of a material that will stand the action of acids. It is often necessary to remove the stains produced with an abrasive powder containing acid, or a dilute liquid acid to ensure proper appearance.

Floors in the bath rooms and hydrotherapy rooms should be cleaned with water containing some efficient antiseptic such as the chlorinated compounds. It is not practical in most bath houses to use foot baths, as the patient must go from one treatment room to another. The floors themselves, therefore, must be thoroughly cleaned and disinfected each day.

Council on Medical Service and Public Relations

THE COUNCIL HAS AUTHORIZED THE PUBLICATION OF THE FOLLOWING
STATEMENT J. W. HOLLOWAY, JR., Acting Secretary

THE WAGNER-MURRAY-DINGELL BILL

The legislation introduced in the United States Senate, June 3, 1941 by Senator Wagner and Senator Murray is S 1161 and in the House of Representatives by Congressman Dingell as H R 2861 proposes radical amendments to the Social Security Act. Others have characterized it as "fantastic in scope, idealistic in objective and extremely expensive in its economic aspect."

The Council reserves judgment on the amendments proposed that are not directly concerned with medical care. Concern must be expressed, however, over the effect on the health of the people of that part of the legislation that undertakes to create a federally controlled system of compulsory sickness insurance to include an estimated 110,000,000 wage earners, self-employed persons and the dependents of both classes. Such a system would be created by section 11 which proposes to amend title IX of the Social Security Act to provide "Federal Medical Hospitalization, and Related Benefits."

By a revolutionary process the enactment of section 11 would undermine and destroy the American system of medicine that has developed in an evolutionary, healthful manner over the entire period of the history of medicine in the United States.

American medicine has developed an unexcelled quality of medical education. The enactment of section 11 would break down our system of medical education. It would remove the incentive that stimulates the student to acquire the best medical education obtainable by offering that student a regimented practice federally supervised and controlled. Thus result the sponsors of the legislation inferentially apprehend by including a provision for federal grants-in-aid to stimulate medical education.

American medicine has made available to the people an unexcelled quality of medical care. The enactment of section 11 would attenuate the quality of medical care available to the people by imposing on physicians conditions of practice under which good medical care could not possibly be rendered. Medical practice would deteriorate from a highly personalized professional service to an impersonal, regimented service.

American medicine has produced unexcelled medical research by individuals. The enactment of section 11 would lessen the incentive for individual medical research by making it impossible for the results of that research to be utilized to their fullest extent. This result the sponsors of the legislation inferentially apprehend by providing for federal grants to *nonprofit institutions and agencies* to encourage and promote research.

American medicine has been responsible for a state of health of the people unexcelled in any other country. The enactment of section 11 would result in a deterioration of the health of the people, for if medical education suffers, if the quality of the medical care available to the people becomes attenuated, if the incentive to individual medical research is removed, the resulting harmful effect on the health of the people will be inescapable.

WHAT DOES SECTION 11 PROPOSE?

Section 11 proposes to amend title IX of the Social Security Act to provide general medical, special medical, laboratory and hospitalization benefits to every person currently insured under the act, to the wives and children of such persons and to certain other groups who may voluntarily bring themselves within the coverage of the act.

To provide these benefits, the Surgeon General of the United States Public Health Service would be authorized to make all

necessary arrangements. He would, in effect, become the autocrat of American medicine. Although every physician legally qualified by a state may, if he consents to regimentation, participate in this compulsory health insurance scheme, the Surgeon General may by regulation prescribe the conditions of participation. He too would be authorized to determine what compensation the participating physicians may receive and would have the final say as to the manner in which they will be compensated, whether on the basis of fees for services rendered, on a per capita basis, on a salary basis or on any combination or modification of these bases. He would be authorized to limit the number of insured persons a particular physician may treat. He would be authorized to determine what constitutes the services of a specialist.

Ostensibly to assist the Surgeon General there will be created a National Advisory Medical and Hospital Council to be appointed by the Surgeon General, of which he will himself be chairman. This council will have no authority, it will be authorized only to "advise." While an insured individual may select, normally, from the list of participating general practitioners the physician to treat him, he will be denied that privilege if the physician's quota of patients, as established by the Surgeon General is already filled. If he is in need of the services of a specialist, he will have no voice in the selection of that specialist. The Surgeon General may arbitrarily assign an insured person to a particular physician if such person does not make his own selection.

The bill provides that in each area the provision of general medical benefit for all insured persons shall be a "collective responsibility of all qualified general practitioners in the area who have undertaken to furnish such benefit." The significance of this provision is difficult to determine. It may signify that each participating physician will be responsible for the quality of medical service rendered by every other participating physician in that particular area.

The Surgeon General would be authorized to determine what hospitals may participate in the scheme. Hospital benefits will range from \$3 to \$6 for each day of hospitalization, not in excess of thirty days as determined by the Surgeon General with the approval of the Social Security Board. The rate will range from \$1.50 to \$4 for each day of hospitalization over thirty but not exceeding ninety. If the insured is placed in an institution for the care of the "chronic sick" the rate will range from \$1.50 to \$3 a day. Instead of making such payments to the insured individual the Surgeon General, subject to the approval of the Social Security Board, may make contracts with participating hospitals for the payment of the reasonable cost of hospital service at rates neither less than the minimum nor more than the maximum rates specified such payment to be full reimbursement for the cost of essential hospital services including the use of ward or other least expensive facilities compatible with the proper care of the patient.

Insured persons will also be entitled to certain laboratory and other benefits, the nature and extent of which will be determined by the Surgeon General but which will include chemical, bacteriologic, pathologic, diagnostic and therapeutic x-ray and related laboratory services, physical therapy, special appliances prescribed by physicians, and eye glasses prescribed by a physician or other legally qualified practitioner.

TAXES TO PROVIDE BENEFITS

To finance the provisions of this bill, each included employer will be taxed annually at the rate of 6 per cent of his payroll excluding all remuneration paid to an employee in excess of \$3,000 a year, and each insured employee will be taxed 6 per cent annually of the wages received up to \$3,000. Self-employed persons will be required to pay 7 per cent of the market value of their services annually up to \$3,000. States and political subdivisions and their employees will be taxed at the rate of 3.5 per cent up to \$3,000 if such governmental units voluntarily by compact come within the coverage of the Social Security Act.

Of this total tax a certain amount will be credited to a "Medical Care and Hospitalization Account," an amount estimated as in excess of \$3,000,000,000 annually

GRANTS-IN-AID

Section 12 of the bill as previously indicated, provides grants-in-aid as a stimulus for medical education, research and for the prevention of disease and disability, in apparent recognition that the enactment of the bill will require such a stimulus. The Surgeon General of the Public Health Service will determine who will be the recipients of such grants and the specific amounts that will be granted. He will determine too whether a particular project is worthy of stimulation.

The enactment of this bill will destroy the private practice of medicine. It will create a political system of medicine dictated by a federal bureaucracy. It will lower the high health level of the people of the United States. Its enactment should be vigorously opposed.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

HOWARD A. CARTER, Secretary

ROCKE HYDROTHERAPY FOOT AND ARM BATH ACCEPTABLE

Manufacturer: William Roche, 2605 Noyes Street, Evanston, Ill.

The Roche Hydrotherapy Foot and Arm Bath is a device for the application of hot, whirling, aerated water (with a vibratory action) to the feet and arms. The apparatus consists of a tank 17 inches in diameter which is mounted on a base 34 inches in height, containing a one-fourth horsepower motor. Incorporated in the tank are a circulator unit, foot plate and air intake.

Eighteen gage steel with three coats of porcelain enamel is used in the construction of the tank. According to the manufacturer this material is used because it can be more easily obtained during the present emergency. The tank is protected on the outside by a steel skirt extending from the base to the top. The inside of the tank is white and the outside is gray. The circulator unit is constructed of die cast aluminum with self-oiling bronze bearings and is direct motor driven. The foot plate and air intake cover are of chrome or cadmium plated steel. A rubber tube with aluminum control valve comprises the air intake. The motor is rubber mounted with three conductor rubber covered cord and is fully grounded.

Roche Hydrotherapy Foot and Arm Bath

The steel tank with three coats of porcelain enamel, together with the steel skirt jacketing the tank, is said to tend to slower cooling of the liquid. The temperature of the liquid while in operation normally drops about 2 degrees in thirty minutes, temperature change also depends on room temperature. An immersion hot water heater is available.

The apparatus was investigated clinically by the Council in the physical therapy department of a large hospital. In this investigation the device was found to satisfy the claims made for it by the manufacturer.

The Council on Physical Therapy voted to accept the Roche Hydrotherapy Foot and Arm Bath for inclusion in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONTRIBUTING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E. SMITH, M.D., Secretary

CHORIONIC GONADOTROPIN (See New and Non-official Remedies, 1943, p. 427)

The following dosage forms have been accepted

WINTHROP CHEMICAL CO., INC., NEW YORK

Vials Korotrin 100 International Units 2 cc A powdered preparation of chorionic gonadotropin admixed with sucrose which, when diluted with the accompanying 2 cc of sterile distilled water containing 0.2 per cent of metacresol, provides a solution having a potency of 50 international units per cubic centimeter. Marketed in boxes of 5 ampuls and 25 ampuls with diluent for each ampul.

Vials Korotrin 500 International Units 2 cc A powdered preparation of chorionic gonadotropin admixed with sucrose which, when diluted with the accompanying 2 cc of sterile distilled water containing 0.2 per cent of metacresol, provides a solution having a potency of 250 international units per cubic centimeter. Marketed in boxes of 5 ampuls and 25 ampuls with diluent for each ampul.

Vials Korotrin 1,000 International Units 10 cc A powdered preparation of chorionic gonadotropin admixed with sucrose which, when diluted with the accompanying 10 cc of sterile distilled water containing 0.2 per cent of metacresol, provides a solution having a potency of 100 international units per cubic centimeter. Marketed in packages containing 1 or 10 vials with 1 or 10 bottles of diluent.

Vials Korotrin 5,000 International Units 10 cc A powdered preparation of chorionic gonadotropin admixed with sucrose which, when diluted with the accompanying 50 cc of sterile distilled water containing 0.2 per cent of metacresol, provides a solution having a potency of 100 or 500 international units per cubic centimeter. Marketed in packages containing 1 or 10 vials with 1 or 10 bottles of diluent.

DIETHYLSTILBESTROL (See New and Nonofficial Remedies, 1943, p. 403)

The following dosage forms have been accepted

THE WARREN-TEED PRODUCTS CO., COLUMBUS, OHIO

Tablets Diethylstilbestrol 0.5 mg and 1 mg

Sterilized Solution Diethylstilbestrol (in sesame oil) 1 mg per cc 15 cc containing 0.5 per cent chlorobutanol

Ampuls Sterilized Solution Diethylstilbestrol (in sesame oil) 1 mg per cc 1 cc

DIGITALIS (See New and Nonofficial Remedies, 1943, p. 289)

The following dosage forms have been accepted

BURROUGHS WELLCOME & CO., INC., NEW YORK

Tabloid Digitalis Leaf 32 mg, 65 mg and 97 mg

THE UPJOHN COMPANY, KALAMAZOO, MICH

Ampoule Sterile Solution Digitalis Injection 2 cc and 10 cc Each cubic centimeter contains 1/2 U.S.P. XII digitalis unit and alcohol 10 per cent as preservative and stabilizer in sterile phosphate buffered solution.

SODIUM MORRHUATE (See New and Nonofficial Remedies, 1943, p. 310)

The following dosage form has been accepted

CHEPLIN BIOLOGICAL LABORATORIES, INC., SYRACUSE, N. Y.

Ampoule Solution Sodium Morrhuate 5% W/V with Tricresol 0.3% 2 cc. and 5 cc ampoules and 30 cc. vials. Each cubic centimeter contains sodium morrhuate 34 grain tricresol 0.3% (W/V) as a preservative double distilled water q.s.

SATURDAY, NOVEMBER 13, 1943

HYPERTENSION IN MILITARY SERVICE

Some persons when exposed to the emotional stress of a physical examination, have a temporary rise in blood pressure which subsides in later readings. Little significance is given to such a transient elevation in blood pressure. Physicians assume that, if one or more readings of blood pressure within the normal range are obtained, the possibility of hypertensive disease can be disregarded. However, due consideration should be given to the fact that in many hypertensive persons the level of blood pressure is variable. Wide fluctuations from normal to high levels may occur in intervals of a few hours, and elevations of blood pressure are readily precipitated by emotional strains. These cases apparently tend to develop ultimately into permanent hypertension. In 1,522 patients reviewed by Hines¹ ten to twenty years after the original examination, a high percentage of those presenting excessive variability of the normal blood pressure developed definite hypertensive disease. Master² reexamined a group of 50 persons who one to seven years previously had shown labile high blood pressure with fluctuations which included normal values. He found that 76 per cent presented definite permanent hypertensive levels. Rühl³ as early as 1927 had interpreted the labile hypertension as the early stage of essential hypertension. There is no clear-cut line of delimitation between the normal person who shows occasionally an increase in blood pressure under various influences and the borderline hypertensive patient. Essentially the two represent different degrees of the same condition.

As would be expected in the light of these observations, the rules established by the Navy for acceptance and rejection of candidates have resulted in the acceptance for active duties of borderline hypertensive

patients. A number of instances in which this condition has led to the development of clinical symptoms and unfitness during active campaign is reported by Master.⁴ The ideal solution would be to reject all persons presenting hypertensive levels at any one reading. However, when statistical figures are considered the incidence of hypertension in the general population would be so high as to prevent the attainment of the minimum goal required by the armed forces.

Considering the implications of this difficult problem, Master suggests that a different approach be adopted. The question of fitness for active duties in the borderline cases is not so much dependent on the height and variability of the blood pressure as on the absence or presence of complications of hypertension. An uncomplicated mild hypertension is compatible with a high degree of physical activity and need not be a cause for rejection. A complete cardiovascular examination, including a roentgenogram of the chest, electrocardiograms before and after exercise tests, examination of the retinal vessels and renal function tests, is necessary in order to determine the presence of cardiac enlargement, myocardial damage, coronary disease, arteriolar lesions and renal insufficiency. On these criteria and not on blood pressure measurements alone should the physician base his judgment as to the suitability of candidates for military service.

CARCINOGENIC TRANSFORMATION OF FIBROBLASTS IN CULTURE FLASKS

Earle and Voegtlin¹ of the National Cancer Institute have demonstrated that rat and mouse fibroblasts grown outside the body in a medium containing methylcholanthrene, a carcinogenic chemical, are changed into cells which resemble the cells in cultures of sarcoma induced by the injection of methylcholanthrene into the subcutaneous tissue of rats. This transformation appeared to be irreversible. Now Earle² reports that sarcoma can be produced by the injection of fibroblasts subjected to the action of methylcholanthrene in culture flasks. When mouse fibroblasts had been cultured in a medium of horse serum, extract of chick embryo and salt solution for 291 days, purified methylcholanthrene was added to the cultures in the proportion of 1 microgram to each cubic centimeter of culture fluid. The cultures were then carried on for different periods, 6, 32, 111, 184 and 406 days, at the end of which they were continued without methylcholanthrene for various periods. The first apparent effect of the carcinogen was

to slow down the rate of the increase in the size of the cell clumps. Later the cells were changed in shape and became increasingly coherent laterally forming ribbons and sheets. These changes in the cells continued in successive cultures after the addition of methylcholanthrene to the culture fluid was discontinued. Two cell strains subjected to the carcinogen for 6 and 32 days respectively have been carried on in carcinogen free cultures for about a year without any loss of the induced characteristics. Some months after morphologic changes were noted in the carcinogen cultures control cultures began to present similar changes. Whether this change in the control cultures was due to the accidental introduction of traces of methylcholanthrene or not will be considered in a later report. "It is thought likely that such trace contamination did occur" but it must have been extremely slight in view of all the precautions against contamination.

On injection into mice (strain C3H) of carcinogen treated cultures of mouse fibroblasts at varied intervals after the withdrawal of the carcinogen, sarcomatous tumors arose at the sites of injections, often as early as 9 days after the injection, and caused death within a few weeks, with or without metastasis. Such tumors were subinoculated successfully. Injections of control cultures with altered cells gave similar results. Nettleship¹ describes the characteristics of the neoplasms which grew from the inoculation of altered fibroblast cultures. The structure was similar to that of the various forms of spindle cell sarcoma in man. Earle and Nettleship both point out that short exposure of cultured fibroblasts to the carcinogen produced cells of a comparatively low neoplastic activity and slightly changed in structure. No metastasis occurred from tumors from these cells. On somewhat longer exposure the cells became more greatly altered morphologically and there was an increased invasiveness into the surrounding tissues. A number of tumors showed metastases. On still longer exposure of the cells to the carcinogen the cell structure of the tumors arising from them was even more greatly changed, the invasiveness was at least as great, but fewer metastases occurred.

The tumors described arose by the multiplication of implanted cells which came from cultures carried on for many months after exposure to methylcholanthrene. It is not likely that the cells carried over any of the carcinogen to which their remote ancestors were exposed. The implanted cells were cancerous, that is, sarcomatous cells which multiplied as such on implantation in living mice. After the change from normal fibroblasts under carcinogenic influences, all subsequent generations were cancerous in greater or lesser degree. This change remained irreversible. While it is not difficult to make normal cells and their descendants cancerous either *in vivo* or *in vitro*, it is not yet known how cancerous cells can be made normal again, that is,

no doubt the secret of cancer. The results of the remarkable experiments briefly recounted suggest ways and means for direct attacks on the problems of the irreversibility of the cancer cell.

Current Comment

EPINEPHRINE-LIKE SUBSTANCES IN THE HEART MUSCLE AND SUDDEN DEATH

The cause of unexpected sudden death can be determined only by thorough postmortem examination the results of which are interpreted in the light of the history of the victim and of the circumstances under which he died. In many such cases chemical methods may be of great value. In an athletic student aged 21 who was found dead in bed the only abnormality discovered by Raab¹ was an excessive amount of epinephrine-like substances or catechols in the heart muscle. Death was not caused by structural changes, by laryngeal obstruction or by poisoning as commonly understood. Raab argues that the death was due to excess of epinephrine-like substances on the basis of the following general considerations. In rats cardiac death takes place when the concentration of such substances in the myocardium exceeds a certain limit, in a series of patients who died from cardiac failure, particularly in cases of hypertension, angina pectoris, uremia and adrenal tumor, he found in the majority an abnormally high accumulation of epinephrine or of epinephrine-like catechols in the heart muscle and, finally, experimental production of fatal heart failure by means of epinephrine and related amines. Raab points out that in human beings, as well as in animals, "severe cardiac episodes and death" have followed the injection of epinephrine hydrochloride, also that ventricular fibrillation, which is regarded as a common cause of sudden cardiac death, may be produced by epinephrine. He notes too the not infrequent reports of rapid death of patients with adrenal tumor, with hemorrhagic necrosis and other lesions of the adrenals. This group, by the way, appears to include cases of death from adrenal insufficiency as well as cases of hyperepinephrinemia. The concentration of epinephrine-like catechols in the heart muscle of the athletic student examined by Raab was not only above the physiologic maximum but the highest in a series of 54 human hearts, normal and abnormal. According to Raab "the most famous case of sudden death of an apparently healthy athlete from 'exhaustion' occurred two thousand four hundred and thirty-three years ago when the marathon runner collapsed, dead, on his arrival in Athens, after having shouted the message of victory over the Persians. It appears most probable from present knowledge that his heart succumbed to ventricular fibrillation due to an acute excessive accumulation of sympathomimetic amines in the myocardium." No doubt the chemical examination of the heart muscle will prove helpful in explaining the nature of sudden deaths, particularly in the case of athletes, but eventually in other cases as well.

DOCTORS AT WAR TO BE RESUMED

Arrangements have been completed with the National Broadcasting Company to resume the series of broadcasts entitled *Doctors at War*. This will be the fourth series of broadcasts under the general title of *Doctors at War* and will be the ninth annual series of dramatized health programs presented cooperatively by the American Medical Association and the National Broadcasting Company. Owing to radio commitments in connection with the war, the opening of the series has been postponed until January 8. Broadcasts will be given on Saturday afternoons at 5 o'clock Eastern War Time (4 o'clock Central, 3 o'clock Mountain, 2 o'clock Pacific War Time). The series will run for twenty-six weeks. The Medical Department of the United States Army and the Bureau of Medicine and Surgery of the United States Navy have agreed to permit doctors in the armed forces to participate in the programs. The medical departments of both the Army and the Navy will assist in the technical preparations for the broadcasts.

DEVELOPMENT OF RESISTANT PNEUMOCOCCI DURING SULFONAMIDE TREATMENT

Experimental evidence that the capacity to acquire resistance to sulfonamide drugs occurs in vivo was offered by MacLean and his associates¹ in 1939. Pneumococci of infected mice treated with sulfapyridine establish an increasing tolerance to the drug. Lowell, Strauss and Finland² in 1940 demonstrated the development of resistance in pneumococci obtained from patients treated with sulfonamide drugs. Sulfonamide sensitive organisms were isolated in 2 cases of pneumonia prior to treatment. After several days of drug therapy and again during a relapse of the pulmonary infection, pneumococci of the same type were isolated and found to be sulfonamide resistant. Recently Hamburger and his colleagues³ studied sulfonamide sensitivity of pneumococci isolated from a great number of patients both before and after sulfonamide therapy. In none of 168 patients were strains of pneumococci isolated before treatment significantly resistant to the drug. The organisms obtained during or after treatment were definitely more resistant than those obtained before treatment in only 4 of 72 cases treated for less than three weeks. In each of 3 cases treated for long periods (forty-seven days or more) resistant pneumococci developed during treatment. This suggests that sulfonamide resistant organisms may be produced regularly during the clinical use of these drugs. Lesions such as occur in unresolved pneumonia, in which the complete eradication of the bacteria requires prolonged and increased concentration of sulfonamides, and in

endocarditis, in which bacteria have only limited exposure to the drugs, offer the ideal conditions for the development of drug fastness. As pointed out by Hamburger and his associates, even though the development of sulfonamide resistant organisms occurs in a relatively small number of cases, this result may constitute a serious hazard in the future.

THE SURVIVAL TIME OF HUMAN SPERMATOZOA

One of the serious obstacles to the scientific evaluation of chemical contraceptives has been the absence heretofore of any uniform method of determining the survival time of human spermatozoa. Brown and Gamble,¹ in a series of communications, report the satisfactory use of potassium acid phthalate as a spermicidal agent. This agent is prepared as a watery solution with a known acidity of $p_H 4.0$. A 28 per cent solution mixed with an equal quantity of semen has been found to give spermicidal times of convenient length. When the spermicidal times are measured at ordinary room temperature the results are arbitrarily referred to as the "phthalate time." Variations in temperature exert a considerable effect on the phthalate time. At body temperature the relative spermicidal times vary significantly from those at room temperature. Variations in phthalate time of different semen specimens have been also found large. Nevertheless this method appears to permit evaluation of the relative spermicidal activities of commercial contraceptives, and a number of such preparations have already been tested by this means. Although this apparently represents a definite addition to scientific method, the several variables attached to the procedure indicate that the conclusions must be cautiously accepted and further careful studies at control attempted.

IMMEDIATE TREATMENT OF WOUNDS AND BURNS

Elsewhere in this issue (page 675) appears an article on the immediate treatment of wounds and burns based on military experience. This work will have far reaching effects on first aid in civilian as well as military life. Many lives can be saved, Gallagher claims, by the early utilization of simple sterile compression dressings to be applied to severe burns or other large surface wounds immediately at or near the scene of injury. The technic is simple and can be employed as a first aid measure by relatively untrained persons. Compression dressings may become standard equipment for all first aid kits. The proper application of these dressings should be made familiar to the police in squad cars, nurses' aides, street car and bus motormen and conductors, firemen, workers in industry and many others.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeons General of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

ARMY

EARLY RECOGNITION AND TREATMENT OF NEUROPSYCHIATRIC CONDITIONS IN THE COMBAT ZONE

The War Department, Washington, D. C., recently released Circular Letter No 176, regarding the early recognition and treatment of neuropsychiatric conditions in the combat zone, which is as follows:

1 *General*—Any medical officer may be called on to treat neuropsychiatric casualties. Because of the shortage of neuro-psychiatrists, the burden of early recognition and treatment of these casualties will fall on medical officers without specialized training. The attention of all medical officers, therefore, is invited to their responsibility for the mental as well as physical health of military personnel.

2 *Incidence*—According to present figures, from 10 to 20 per cent of casualties developing in combat are neuropsychiatric and, in certain engagements, as high as 30 per cent are of this type. It has been found that, when these cases are properly recognized and treated at forward areas, up to 80 per cent can be returned successfully to combat duty, whereas, when improperly evaluated and unnecessarily evacuated to rear areas, only from 5 to 10 per cent can be returned to duty.

3 *Etiology*—a Ordinarily neuropsychiatric disorders are thought to occur only in weaklings or in individuals with personality defects. This is not true. Information at hand indicates that a significant proportion of the neuropsychiatric casualties are occurring in individuals who give no history suggesting predisposition. Under the extremes of stress and fatigue of modern combat, the most stable individual may reach his breaking point. Thus, the presence of neuropsychiatric disorder must be looked for in normal as well as predisposed individuals.

b Factors which precipitate psychiatric disorders are separation from home, regimentation, lack of freedom, lack of privacy, lack of feminine companionship, a feeling of not being appreciated and lack of confidence in leaders. In combat are added extreme fatigue, danger of death and mutilation, exposure to cold, heat, disease, isolation, confusion and hunger. The danger of being a coward, of losing self control, as well as responsibility for the lives of others, also plays a role. Insufficient understanding and conviction regarding the need to fight are also factors.

4 *Clinical Types and Diagnoses*—a Considerable confusion exists as the result of current use of diagnostic terms, such as 'operational fatigue,' 'shell shock' and 'war neurosis.' There is no evidence that any new clinical entity has appeared in this war which would warrant the employment of these terms. It is directed that standard nomenclature for psychiatric disorders be utilized wherever possible.

b In certain theaters it has been found that the term "psychoneurosis" produced in the patient's mind the idea of war causation and incurability and thus materially interfered with recovery. The term 'exhaustion,' on the other hand, implied to the patient nonspecific etiology, natural occurrence and speedy recovery. It was also in a measure true in that in the majority of cases this exhaustion was a strong contributory factor. If it is found expedient to use the term "exhaustion" as a preliminary diagnosis for combat neuropsychiatric casualties, the term should

be employed only on the emergency medical tag (M. D. Form 52b) and the case redesignated with the proper psychiatric term on the field medical record (M. D. Form 52c). The use of the term "exhaustion" for psychoneurosis will be confined to cases developing under enemy action. Cases of exhaustion free from psychiatric components and essentially "physical" in nature will be qualified with an appropriate term in addition to the word "exhaustion" for purposes of differentiation.

c Psychiatric casualties fall into the following main groups and should be so labeled:

- (1) *Psychoneuroses* These comprise the vast majority of neuropsychiatric casualties in the combat zone. They occur either in a normal or an emotionally unstable individual. Underlying domestic difficulties frequently play a role. The types of psychoneuroses encountered are as follows:
 - (a) *Anxiety* The anxiety type is the most common. The anxiety symptoms show pronounced variations in severity, but certain symptoms are common to all of them. The most striking of these manifestations is the inappropriate reaction to any sudden sound, sudden movement or the sound of motors of any description. When these stimuli occur, the patient immediately concentrates all attention on the sound or, in more severe cases, may immediately run or seek cover of some sort and exhibit all the symptoms of a minor panic state. This reaction cannot be said to be abnormal qualitatively, since it is the normal reaction, to a lesser degree, of all men who have experienced combat conditions, but the quantitative response is clearly exaggerated. With this abnormal response there is usually a variable degree of mental confusion, tachycardia, tremors and, if severe, vasomotor reactions of the sympathetic type are evident. In addition, they manifest all of the anxiety reactions evident in civil life, namely, night terrors, insomnia, irritability, inability to concentrate, tremor and somatic symptoms of the visceral type.
 - (b) *Hysteria* The hysterical reactions of paralysis, anesthesia, deafness, blindness and aphonia, so common in the last war, are notable for their rarity. Of the hysterical reactions seen, the rhythmic reflex tremors, repetitive dodging and avoiding movement, amnesias and stupor reactions are by far the most common. These manifestations are extremely dramatic in character and in general show a very poor response to therapy in that, when they are resolved, anxiety or other hysterical manifestations replace them or they recur under very minor stress. Some of these cases are distinguished from true psychotic reactions with great difficulty. They may show clearcut hallucinatory reactions, thought block, retardation, decidedly childish behavior and little insight.
 - (c) *Psychasthenia, neurasthenia and reactive depression* are seldom seen and when seen do not respond rapidly.
- (2) *Psychoses* Psychoses rarely occur in normal individuals but may be precipitated in unstable individuals by stress of battle. The clinical pictures do not differ from those seen in the zone of interior. When the manifestations are

bizarre and dramatic, or when hallucinations and delusions are present detection is not difficult. Psychoses may also be manifested merely by overtalkativeness, overactivity, distractibility, depression, apathy, indifference, carelessness in the care of clothes and eating habits or by undue suspiciousness or complexes on particular subjects such as the government or religion. Psychoses also occur which appear to be full blown cases of schizophrenia but differ from the true disease by clearing up in a matter of days or weeks.

(3) **Psychopathic Personality** Psychopathic personalities with homosexuality, emotional instability or asocial and amoral trends are of course revealed but not caused by the stress of battle. Individuals with these personality defects are more likely to become psychiatric casualties than are "normal" individuals.

(4) **Mental Deficiency** Limited intelligence also is revealed rather than caused by combat and may be mistaken for hysterical confusion or stupor.

(5) **Organic Neurologic Disease** **Concussion Due to Blast** An individual may be within a few feet of a bursting shell and suffer no organic damage, whereas another individual many yards from the same burst may be killed outright by the concussion. The individual who has suffered organic damage from blast almost invariably gives a history of clear loss of consciousness, having his breath knocked out, coughing up blood, sputum or bleeding from the ears and nose. On examination he may show fissuring of the skin, flash burn, perforated or hemorrhagic eardrums, conjunctival hemorrhage, signs of intrathoracic or intra-abdominal pathologic changes, focal or general signs of organic damage of the central nervous system.

5 **Malingering**—A common error is to mistake psychoneurosis for malingering. It is difficult for many to accept the fact that malingering and psychoneurosis are distinct clinical entities. Treatment effective for one is utterly useless and even harmful for the other. Malingering is the conscious, deliberate exaggeration or pretense of an illness for the purpose of escaping duty. Psychoneurosis is an actual illness. By definition, a malingerer lies about his symptoms. A person with psychoneurosis either tells the truth or what he firmly believes is the truth. It may be true that neither wants to return to duty, but the malingerer is aware that he could go back if he chose, whereas a person with psychoneurosis either is actually unable to return to duty or sincerely believes so.

6 **Disposition**—a It is highly important to avoid indiscriminate evacuation. If a case can be treated adequately in forward areas, the prognosis is, as a rule, far better. On the other hand, delay in evacuating cases for which specialized treatment in a base area is necessary may prove disastrous to the patient and harmful to the efficiency and morale of the unit.

b The criterion for selection of cases is the length of time which will be necessary to return a given case to effective duty. In general, the evacuation policy is to retain at the level of the evacuation hospital only those who require five days' treatment or less. All other cases must be treated in hospitals further removed from the front. In a general way, the accompanying table, based on actual field experience, may serve as a guide.

7 **Treatment**—a Treatment of neuropsychiatric cases developing in the combat zone is based on four cardinal principles:

- (1) Early selection of cases which with treatment may be returned promptly to duty.
- (2) Treatment of these cases in the combat zone.
- (3) The rapid initiation of sedation in all cases.
- (4) Recognition that psychiatric casualties are not malingerers needing punishment but sick men needing treatment.

b **Treatment in the Division Area** Battalion or regimental medical officers can return many mild cases to duty in a few hours by means of discussion, reassurances and short rest periods in the unit rest area. Heavy sedation should be initiated when the patient is first seen. This heavy sedation acts to raise the stimulus threshold, decreases the anxiety reaction and

decreases the abnormal suggestibility. The dose given must not be sufficiently high to convert a sitting case into a litter case. The sedation of choice is sodium amytal 6 to 9 grains (0.4 to 0.6 Gm) orally or an equivalent dose of a similar rapidly acting sedative. Phenobarbital $4\frac{1}{2}$ grains (0.3 Gm) may be used, but the slowness of its action is a disadvantage in an acutely excited patient. Intravenous medication is to be avoided in forward areas because it converts a sitting into a litter patient and it is only rarely necessary. Morphine should not be used. If there is delay in the collecting or clearing station (and the patient cannot immediately be returned to duty), further sedation is given to keep him in a drowsy state. Doses of sodium amytal up to 15 grains (1 Gm) or phenobarbital up to 8 grains (0.5 Gm) in twenty-four hours may be given with safety.

c **Treatment at the Evacuation Hospital** Immediately on arrival, a rapid examination of the patient is made in order to classify him either for further evacuation on criteria previously discussed or retention in the hospital for treatment. Those retained should be sent to a separate neuropsychiatric ward, allowed to wash, have the ward rules explained to them and a more exhaustive history and physical examination given. On the basis of this more complete examination, those men with

Evacuation Policy for Psychiatric Cases

Retain	Evacuate Immediately	Doubtful
1 All psycho-neuroses of the anxiety type except the most severe	1 All psychoses 2 All organic neurologic disorders 3 All psychiatric repeaters 4 Psychoneuroses with visceral somatic symptoms	1 Moderately severe psychoneuroses of hysteria type 2 Minimal concussion due to blast 3 Mild psychopaths of criminal and aggressive types
2 Mild psycho-neuroses of the hysteria type	5 All severe mental defectives 6 All severe psychoneuroses of the hysteria type (stupors, amnesias, reflex tremors and ties) 7 Severe psychoneuroses of the anxiety type 8 Severe and moderate reactive depressions and psychasthenias 9 Definite psychopathic personality 10 Most cases of concussion due to blast 11 Severe mental defectives	4 Moderate mental defectives 5 Mild reactive depressions

profound disturbances are evacuated the following day. Those remaining, whose prognosis seems good, are given explanations for their symptoms, strong reassurance and suggestions and are then sent to bed for two or three days. While in the ward they are given phenobarbital routinely and additional sodium amytal, if necessary, so that most of their time is spent sleeping. All patients are required to be up for each meal, which they get by standing in line with the up-patients, and to keep their own bed and immediate ward area in order. These steps are taken deliberately to maintain a sense of discipline and to discharge any idea of serious or physical illness. All therapeutic discussion is carried out in the open ward with the idea of repetitive mass treatment effect. Intravenous barbiturate catharsis and suggestions may be used in selected cases. Sedation is discontinued for a full day before discharge, and during this time the decision is made whether to return the patient for further duty or to evacuate him to the communication zone. This decision is based on numerous factors, but response to the direct questions "How do you feel now?" and "Do you want to return to your unit for duty?" are very often the deciding factors. There is no use in returning a man who boldly states that he is certain that he will have further trouble. Little attention is paid to new or minor symptoms except to minimize them and give strong reassurance. No case should be kept in the evacuation hospital over five days.

Executive Officer

BOLLING FIELD BASE HOSPITAL

Until a few years ago Bolling Field, D C, was served by a small dispensary station and was otherwise dependent on Walter Reed General Hospital for cases requiring hospitalization. Col James F Brooke, base surgeon and senior flight surgeon, who arrived at Bolling Field about five years ago and who is at present in command of the base hospital, deserves credit for his efforts which made possible the building of the new hospital. When the hospital was opened in May 1941 the main barracks, which had formerly housed the dispensary, was turned into the flight surgeon's office, where Lieut Col Bernard L Jarman, chief of the flight surgeons' section, is now in charge. Among others on the hospital staff at present are Capt Floyd Fortuin, psychiatrist, Capt Spenser C Flo, who is in charge of the surgical section, Capt Floyd K Hurt, x-ray specialist, who directs this department at the hospital, and Major Timothy F Moran, chief of the eye, ear, nose and throat section.

ARMY SURGEON CITED BY NAVY

Capt Beverly D Hairfield, M C, U S Army, formerly of Charlottesville, Va, received a special citation from the Navy for his work during the Sicilian invasion, having been detached from the evacuation hospital when he volunteered for the assignment. Dr Hairfield graduated from Vanderbilt University School of Medicine, Nashville, in 1939. He entered the service July 1, 1942, when he was commissioned a first lieu-

tenant, and was recently promoted to captain. Regularly assigned to an evacuation hospital which has been in North Africa, Dr Hairfield has been in the surgical division. He landed in Casablanca in the invasion of North Africa and moved close behind the advancing lines to Bizerte and Tunis.

FLIGHT SURGEONS' ASSISTANTS

A class of twenty-six flight surgeons assistants completed the course in aviation medicine at the School of Aviation Medicine, Randolph Field, Texas, October 9. Brig Gen Eugen G Reinartz, U S Army, is commandant of the school.

ARMY PERSONALS

A letter from Capt Charles H Fleck, dated September 23, was recently received by the public safety director of Altoona, Pa, in which was enclosed a Jap souvenir, presumably a chart for temperature and pulse readings, 15 by 12 inches in size and of exceedingly fine, white paper, evidently made of rice. Dr Fleck also stated that when his contingent took possession of an island after the Japs had fled they found that the enemy had left behind most of their possessions except their arms. They had dug caves and tunnels, and their medical and other stores were found intact by the allied soldiers. Dr Fleck is in the medical corps and in service in General Douglas MacArthur's army in the south Pacific. He graduated from George Washington University School of Medicine Washington, D C, in 1932 and entered the service early in 1943.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their Procurement and Assignment Service quotas for Jan 1, 1944.

1 Prospective interns who have not yet obtained a hospital appointment should communicate with these institutions either directly or through the office of the dean of their medical school. Assistant residents and residents should direct their applications to the hospital superintendent in the usual manner.

2 Institutions having a shortage of interns or residents are again invited to make their needs known to the Council on Medical Education and Hospitals. In reporting shortages, hospitals should indicate the number of interns, assistant residents and residents needed to complete their quotas for Jan 1, 1944.

MISCELLANEOUS

HOUSE COMMITTEE DENIES FUNDS FOR RELOCATED PHYSICIANS

Attention was directed in THE JOURNAL, October 16, to the fact that supplemental estimates had been submitted by the President to the Congress for additional funds to enable the United States Public Health Service, either through its own personnel or by the payment of monthly stipends to civilian physicians, to provide medical services in certain critical areas. The House Committee on Appropriations has now reported to the House the First Supplemental National Defense Appropriation Bill for the fiscal year ending June 30, 1944, H R 3598, and has failed to include therein the additional appropriation requested. In explanation of its failure to provide the additional sums, the committee in its report said:

"The budget request contains an item of \$1,000,000 for emergency medical care to provide doctors for areas, principally war industry areas, where the number of civilian physicians and dentists is inadequate for normal medical attention of the population. The amount contemplated \$573,000 for salaries and travel of 300 commissioned officers of the Public Health Service for such assignments and \$375,000 for three months' pay (\$750 each) and travel expenses (\$500 each) for the relocation of 300 private physicians. The committee has not approved this request.

"Undoubtedly a critical situation exists in many areas due to the recruitment for the armed forces of approximately 50,000 doctors. The committee is advised that there are approximately 185,000 doctors in the United States counting those up to 101 years of age. Of these the armed forces have taken 50,000, leaving 135,000 doctors in the country available for the civilian population. An estimate made to the committee by a prominent medical authority indicates that some 40,000 to 50,000 of the 135,000 are ineffective practitioners, leaving approximately 85,000 to 95,000 effective physicians to do the work formerly done by the larger number. The Public Health Service advises that there are in the United States at this time some 213 communities that need physicians and dentists with a minimum need of 295 physicians and 53 dentists. This list is printed commencing on page 979 of the hearings. The survey of need throughout the United States is still incomplete. Surgeon General Parran has advised that in his opinion the situation in many areas is acute.

The committee in rejecting the budget request does not minimize the need or the seriousness of the situations which exist. It does hesitate to inaugurate a program of this character with federal funds to provide direct medical attention to the civilian population with physicians paid by the federal government. The committee has the opinion that out of the cooperative efforts of the federal government, the medical associations, the state departments of health and the communities themselves there will and should come a concerted and spontaneous effort to provide this need. Most of it is in war industry areas and it is inconceivable that such communities working with the industries, the affected population and state and local authority cannot inaugurate and maintain an adequate public spirited program financially sound, to serve this need. If the affected areas cannot and will not solve their local needs it may be necessary for the federal government in the interest of the general public health to step in but until then the committee feels that federal funds should be withheld under the contemplated procedure.

WARTIME GRADUATE MEDICAL MEETINGS

A Wartime Graduate Medical Meeting was held Friday October 29 at the O'Reilly General Hospital in Springfield, Mo. for the medical officers of O'Reilly, Fort Leonard Wood, Camp Crowder and the civilian doctors of the Eighth Councilor District of the Missouri State Medical Association. The program included the following papers: Penicillin Therapy, Major Edward P. Burch, Present Day Status of the Sulfonamides, Dr. Paul Hageman, Tropical Diseases and Malaria, Dr. Russell Blattner, Trauma of the Abdomen, Dr. L. P. Engel, Reconstructive Surgery of War Wounds, Major William S. Kiskade-

den, Psychiatric Problems in General Hospitals, Capt. Clarence M. Schrier, Low Back Pain and Disability, Orthopedic Point of View, Dr. Frank D. Dickson and Capt. William H. Merde.

The attendance was 300, about equally divided between medical officers and civilian doctors. Among the civilian group were men from all parts of the state, with councilors and officers of the state association well represented.

GERMAN DRUGS AND PHARMACEUTICALS SEIZED

According to the Office of War Information, Alien Property Custodian Leo T. Crowley announced on October 21 the seizure by his agents at San Juan, Puerto Rico of twenty-five cases of German drugs and pharmaceuticals estimated to have a sales value of more than \$100,000. The seized medicinal products which originated in La Quimica Bayer, S. A., of Buenos Aires, Argentina, a wholly owned subsidiary of I. G. Farbenindustrie of Germany, were consigned to the German Bayer subsidiary in Venezuela. The seizure of this cargo is a major blow at the German Bayer organization in Venezuela which has not received a shipment since October 1942 and which consequently is almost without supplies. The merchandise in the seized cargo is in sufficient volume to have carried their business for almost a year. The financial loss to the Bayer subsidiary in Argentina as a result of the seizure is also considerable. Assurances have been given to the Venezuelan government that the seizure will not be allowed to jeopardize the public health in that country.

MEDICAL AND SURGICAL RELIEF COMMITTEE OF AMERICA

The Medical and Surgical Relief Committee of America, 420 Lexington Avenue, New York City, presented medical and surgical equipment to set up a battle dressing station on the cruiser the U. S. S. *Boston* to Rear Admiral Luther Sheldon Jr. (MC), U. S. N., who accepted the donation in the name of the Secretary of the Navy, Frank Knox. The equipment consisted of an emergency medical field set, an operating kit and supplemental instruments.

More than \$1,000 worth of surgical equipment was also donated by the Medical and Surgical Relief Committee to the French Red Cross in Algiers, North Africa, to help rehabilitate wounded French soldiers and to relieve the shortage of critical medical supplies. This donation makes a total of more than \$8,000 worth of medical and surgical equipment sent by the committee to North Africa during the past five months.

PUBLIC HEALTH UNDER HITLER

According to the *Frankfurter Zeitung* of August 21 a report from Berlin says that over 5,500 factories today are cared for by works doctors. The question has been repeatedly raised whether the workers of these factories are under an obligation to let themselves be examined by the works doctor on demand in the case of inability to work. According to the present conception of law this obligation exists only if it is explicitly laid down in the wages and factory regulations or in individual labor contracts. A general obligation to submit to an examination by the works doctor did not exist until now. The Office for Social Self Responsibility of the DAF has expressed its opinion that this conception can no longer be maintained. The employer is responsible for the orderly working effort of his workers. Therefore he must be able, if necessary, to let the works doctor establish whether the worker is capable for work or not. The worker's duty of loyalty therefore demands that he submit to examination by the works doctor.

Iolya Plovdiv, of July 9 states that in autumn the chief public health directorate will open a hospital in Sofia for children suffering from infantile paralysis. Children whose parents cannot look after them properly will be treated there.

ORGANIZATION SECTION

OFFICIAL NOTES

ANNUAL CONFERENCE OF SECRETARIES AND EDITORS

The Annual Conference of Secretaries and Editors of Constituent State Medical Associations will be held at the offices of the Association in Chicago on November 19 and 20. The program will be as follows:

FRIDAY, NOVEMBER 19, 10 A M

Call to Order. Roger L Lee, Chairman of the Board of Trustees of the American Medical Association.

Address: James I. Pugh, President of the American Medical Association.

Problems Relating to Assignment of Duties of Military Surgeons. George F. Hull, Deputy Surgeon General, United States Army.

Hospital Training of Medical Graduates. Victor Johnson, Secretary, Council on Medical Education and Hospitals of the American Medical Association.

12:30 p m. Lunch at the Kensington, corner of Ontario and Rush streets.

FRIDAY, NOVEMBER 19, 2 P M

Address: Herman I. Kretschmer, President Elect of the American Medical Association.

Cooperative Relationship of Procurement and Assignment Service and State Medical Associations. Harold S. Diehl, member, Directing Board, Procurement and Assignment Service for Physicians, Dentists and Veterinarians.

The War Participation Committee as a Coordinating Agency. Walter I. Donaldson, chairman, War Participation Committee of the American Medical Association.

The Work of the Council on Medical Service and Public Relations. Louis H. Bauer, chairman, Council on Medical Service and Public Relations of the American Medical Association.

FRIDAY, NOVEMBER 19, 6:30 P M

DINNER MEETING OF EDITORS OF STATE MEDICAL JOURNALS
PALMER HOUSE, CRYSTAL ROOM

Wingate M. Johnson, editor of the North Carolina Medical Journal, presiding.

The Council on Pharmacy and Chemistry. Austin E. Smith, Secretary, Council on Pharmacy and Chemistry of the American Medical Association.
The Cooperative Medical Advertising Bureau. Open discussion.

SATURDAY, NOVEMBER 20, 9:30 A M

Medical Legislation in Congress. J. W. Holloway Jr., director, Bureau of Legal Medicine and Legislation of the American Medical Association.
Obstetric and Pediatric Care for the Wives and Children of Service Men. L. I. Arnold Foster, secretary of the Michigan State Medical Society.

ELECTRICAL TRANSCRIPTIONS IN HEAVY DEMAND

Electrical transcriptions for radio broadcasting for local medical societies prepared by the Bureau of Health Education in two series, American Medicine Serves the World at War and Before the Doctor Comes, became available September 1.

The entire supply available is now in use. An advance schedule is being maintained. Medical societies and auxiliaries desiring the use of transcriptions should file applications for advance dates with the Bureau of Health Education.

The series Before the Doctor Comes consists of sixteen broadcasts in interview form giving advice to the mother as to what to do and what not to do under certain circumstances "before the doctor comes." The series American Medicine Serves the World at War began with six interviews dealing with wartime problems and how they are being solved in various localities. Two additional broadcasts will soon be added to the series, which will be augmented from time to time as opportunity arises.

The Bureau of Health Education is beginning preparations for a third series of transcriptions entitled Contagious Diseases in the Home. This series should be ready approximately Feb 15, 1944.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Change in Status—H. R. 3598 has passed the House, making appropriations to supply deficiencies in certain appropriations for the fiscal year ending June 30, 1944 and to provide supplemental appropriations. As reported to and passed by the House, this bill fails to appropriate the amount requested by the President for emergency medical care to provide doctors and dentists for areas where the number of civilian physicians and dentists is inadequate for normal medical and dental attention of the population. The bill does include a supplemental appropriation of \$7,500,000 for the training of nurses and an appropriation of \$10,356,000 to provide additional hospital and domiciliary facilities for veterans. The committee report indicates that this amount will be expended to provide facilities for neuropsychiatric patients.

Bills Introduced—H. Con. Res. 51, submitted by Representative Schaffler, West Virginia, proposes to request the Social Security Board to create a special advisory council to investi-

gate the extension of the federal old age and survivors insurance system to include persons in the armed forces, and also the extension of unemployment allowances after termination of military service. H. R. 3603, introduced by Representative Summers, Texas, proposes to regulate the commitment of insane persons to veterans' and other United States institutions. H. R. 3610, introduced by Representative Rowan, Illinois, provides for a program of research in universities, colleges and other institutions of higher learning, for the prevention of the pollution of the waters of the United States and to establish a Water Pollution Control and Sewage Utilization Board, to be composed of the Secretary of Agriculture, the Surgeon General of the Public Health Service and one other person to be appointed jointly by the Secretary of Agriculture and the Surgeon General. H. R. 3623, introduced by Representative Rogers, Massachusetts, proposes to establish a permanent medical service in the Veterans Administration which will constitute a component part of the military forces of the United States.

WOMAN'S AUXILIARY

Kansas

The Wyandotte County Medical Auxiliary recently held a dessert luncheon and book review, at which time they reported fifteen new members.

The Sedgwick County auxiliary decided to hold only three meetings during the year. Mrs. James Hibbard, Wichita, is the new president.

At a meeting of the Kansas auxiliary recently the following officers were elected:

Mrs. E. E. Tippin, Wichita, president; Mrs. Leo J. Schaefer, Salina, president-elect; Mrs. C. D. Blake, Hayes, first vice president; Mrs. M. A. Brawley, Frankfort, second vice president; Mrs. H. L. Regier, Kansas City, secretary; and Mr. E. N. Robertson, Concordia, treasurer.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SPENDING FOR THIS DEPARTMENT ITEM OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

ARKANSAS

Dr Pelouze to Lecture on Gonorrhea—Dr Percy S. Pelouze, associate professor of urology, University of Pennsylvania School of Medicine, Philadelphia, and special consultant for the gonorrhea control program of the U. S. Public Health Service, will address county and district medical societies in Arkansas, March 13-24, under the auspices of the public health service.

District Meetings—The Fifth Council District Medical Society was addressed in Camden, October 7, by Drs. Henry King Wade, Hot Springs National Park, on "Cancer of the Prostate"; Joseph F. Shuffield, Little Rock, "Fractures of the Hip"; Byron L. Robinson, Little Rock, "Medical Education"; and William R. Brooksher, Fort Smith, "The Wagner-Murray Bill."—The First Council District Medical Society of Northeast Arkansas held its eighty-second semiannual meeting in Jonesboro, October 21, with the following speakers: Capt. Louis J. Benton, M. C. A. U. S., on "Some Uses and Disuses of the Sulfonamides"; Lieut. Harry Cohen, M. C. A. U. S., "Practical Consideration in Treatment of Early Syphilis"; Dr. Pearl W. Lutterloh, Jonesboro, "Highlights of the Wagner Bill"; and Dr. Robert H. Willett, Jonesboro, "Relative Value of Deep X-Ray Therapy in Lobar Pneumonia."

CALIFORNIA

Dr. Wagner Placed in Charge of Tuberculosis Control—Dr. William F. Wagner, resident physician at Olive View Sanatorium, Olive View, has been appointed chief of the division of tuberculosis control in the San Francisco city and county department of health.

Medical Missionary Repatriated—Dr. Ralph C. Lewis, Shunteh Hopeh, China, medical missionary to China, is expected to be among the exchange prisoners aboard the *Gripsholm* newspapers recently reported. Dr. Lewis was with the American Presbyterian Mission, Hugh O'Neill and Grace Talcott Memorial Hospital, Shunteh.

Vesalius Celebration—The California Academy of Sciences met on October 6 at the University of California Medical School, San Francisco, to observe the 400th anniversary of the publication by Vesalius of "De Humani Corporis Fabrica." The principal address was delivered by Dr. John B. De C. M. Saunders, chairman of the department of anatomy, on "Andreas Vesalius, the Anatomist."

Latin American Gives Herzstein Lectures—Dr. Oscar Ivamissevich, professor of surgery and director of the Surgical Institute of the University of Buenos Aires, will deliver the Morris Herzstein Medical Lectures for 1943 in San Francisco in November under the auspices of the medical schools of Stanford University and the University of California. Dr. Ivamissevich, who is serving as exchange professor of surgery at Stanford University School of Medicine during October and November, will speak November 15 on "General Consideration of Echinococcosis," November 17 on "Echinococcosis of the Liver," and November 19 on "Echinococcosis of the Lung."

COLORADO

State Medical Election—Dr. Edward R. Mugrage, Denver, was chosen president-elect of the Colorado State Medical Society at the recent annual meeting of the house of delegates in September and Dr. George P. Lingenfelter, Denver, was installed as president. Dr. George M. Myers, Pueblo, was chosen vice president. Dr. John S. Bouslog, Denver, is secretary.

The Friedman Lectures—Dr. Walter S. Maclay, medical officer in charge of the Mill Hill Emergency Hospital, London, England, delivered the Friedman Lectures on November 2 and 3 under the auspices of the National Jewish Hospital, Denver, in cooperation with the Medical Society of the City and County of Denver and the University of Colorado School of Medicine, Denver. The first lecture was entitled "Newer Developments in the Neuroses—Their Significance in General Medicine" and a second in the form of a conference, conducted by Drs. Maclay,

Bradford J. Murphy and Charles A. Rimer, Denver, on "Psychosomatic Problems." Dr. Maclay is touring the United States under the auspices of the American Psychiatric Association.

ILLINOIS

Dr. Earle Returns from Latin America—Dr. Walter C. Earle, who has been supervising a federally financed health and sanitation program in Latin America, principally on malaria, has returned as director of the Chicago Urban Public Health District. During his absence his work was carried on by Dr. Raymond A. Brokaw, Springfield, director of the division of cancer control of the state department of public health.

Physician Repatriated—Dr. Albert M. Dunlap, native of Saxony, who had practiced medicine in China since 1910, is being repatriated. He is expected to arrive aboard the *Gripsholm* in New York about December 2. Dr. Dunlap graduated at Harvard Medical School, Boston, in 1910, going to China the same year. Four years later Dr. Dunlap joined the Peiping Union Medical College, Peking, serving as professor of otolaryngology and from 1926 to 1928 as dean of the college.

Dr. Watson Named Chief Medical Officer—Dr. James Watson, director of the division of mental hygiene, North Carolina State Board of Charities and Public Welfare, Raleigh, has been appointed chief medical officer in the Illinois State Department of Public Welfare to succeed Dr. Conrad S. Sommer, who recently became deputy director of the mental hygiene service in the department of public welfare (*THE JOURNAL*, October 23, p. 495). Dr. Watson, in his position as chief medical officer, will be responsible for the medical care and treatment of patients in state hospitals. His new appointment will be effective December 1.

Chicago

Meeting on Tropical Diseases—A joint meeting of the Chicago Medical Society and Aux. Plaines Branch, November 17, will be devoted to a consideration of tropical diseases. Lieut. John E. Choisser (MC), U. S. Naval Reserve, will speak on "Filariasis" and Lieut. Philip A. Arling (MC), U. S. Naval Reserve, "Malaria."

The Bacon Lectures—Dr. Louis E. Phancof, professor of gynecology, Tufts College Medical School, Boston, will deliver the Charles Sumner Bacon Lectures for 1943-1944 at the University of Illinois College of Medicine, December 1-2. Dr. Phancof's subjects will be "Some Notes on the Life of J. Marion Sims, and on the History of Vesico-Vaginal Fistula" and "The Management of Complete Lacerations of the Perineum and Recto-Vaginal Fistula."

Course in Electrocardiographic Interpretation—A course in electrocardiographic interpretation for graduate physicians will be given at Michael Reese Hospital by Dr. Louis N. Katz, director of cardiovascular research. The class will meet each week starting Thursday, February 17, for twelve weeks from 7 to 9 p. m. Further information and a copy of the program may be obtained on application to the Cardiovascular Department, Michael Reese Hospital.

Meeting of Bacteriologists—The fall meeting of the Society of Illinois Bacteriologists will be held in the Chicago Illini Union, November 19. The speakers will be John C. Sylvester, Ph.D., North Chicago, Ill., on "Penicillin Production and Clinical Value"; Albert Milzer, Ph.D., and Drs. Philip Lewin and Sidney O. Levinson, co-authors, "The Effect of Fatigue, Chilling and Trauma on Resistance to Experimental Polymyolitis," and Dr. Henry M. Lemon, Henry Wise, M.S., and Dr. Morton Hamburger, Chanute Field, Ill., co-authors, "A Study of the Bacterial Contents of the Air of Army Barracks."

Personal—Dr. Herman L. Kretschmer, President-Elect of the American Medical Association, received the honorary degree of doctor of science from Marquette University School of Medicine, Milwaukee, during its commemoration exercises, October 18. Dr. Kretschmer gave the commencement address, entitled "Medical Education: The War and You."—Dr. William W. Bauer, Director of the Bureau of Health Education of the American Medical Association, has been elected to the governing council of the American Public Health Association for a three year term expiring in 1946.—Dr. Raymond J. L. Norrby has been appointed assistant to Dr. William H. Haines, director of the Cook County Behaviour Clinic.

Anatomists Honored—Reuben M. Strong, Ph.D., professor and chairman of the department of anatomy at Loyola University School of Medicine, and Thesle T. Job, Ph.D., professor of anatomy, were honored at a dinner in the Medinah Club, October 31, given by the student body, marking their

completion of twenty-five years as members of the faculty. Speakers at the dinner included Dr. Raymond B. Allen, dean, University of Illinois College of Medicine, Dr. Basil C. H. Harvey, professor emeritus of anatomy, University of Chicago School of Medicine, Leslie B. Arce, Ph.D., embryologist, Dr. John I. Keeley, assistant clinical professor of surgery at Loyola, and Rev. Joseph M. Egan, S.T., president of Loyola.

Dr. Anderson Joins American Medical Association—Dr. George K. Anderson, technical aide, division of medical sciences of the National Research Council, Washington, D. C., became Secretary of the Council on Foods and Nutrition of the American Medical Association November 4. Dr. Anderson graduated at the University of Rochester School of Medicine and Dentistry, Rochester, N. Y., in 1938, serving his internship at the Strong Memorial Hospital in Rochester. After he completed residencies at the Children's Hospital, Cincinnati and at the Strong Memorial Hospital, Dr. Anderson served as pediatric consultant for the North Carolina State Board of Health and professor of pediatrics at the University of North Carolina School of Public Health, Chapel Hill.

Graduate Course in Endocrinology—On October 11-16 a graduate course in endocrinology was given as a part of a postgraduate program of the American College of Physicians in cooperation with the University of Illinois College of Medicine and the Presbyterian Hospital under the direction of Dr. Willard O. Thompson. Seventy-four registrations represented the following states and Canadian provinces: California, Colorado, Delaware, Florida, Illinois, Indiana, Iowa, Kentucky, Louisiana, Michigan, Minnesota, Mississippi, Nebraska, New Mexico, Ohio, Pennsylvania, South Dakota, Texas, Utah, Wisconsin, Alberta and Ontario. Most of the attendants at the course are engaged in the practice of internal medicine in their respective communities and many are working in special clinics devoted to the study of endocrine diseases.

INDIANA

Personal—Dr. Herman M. Baker, Evansville, was chosen president of the Indiana State Board of Health at its meeting recently. Dr. Baker has been a member of the board for a number of years and has also previously served as president. —Dr. William D. Weis, Crown Point, health commissioner of Lake County, on September 4 was elected president of the Old Settlers and Historical Association. —Dr. Bertis C. Gwaltney, Fort Branch, health officer of Gibson County, has been appointed assistant collaborating epidemiologist of Indiana.

Stream Pollution Board—The creation of a state stream pollution control board was made possible under the enactment of 1943 legislation. Members of the board include Leo Besozzi, consulting engineer of Hammond, George C. Hillenbrand, manufacturer, Batesville, Joseph L. Quinn, technical secretary of the board, appointed by the state board of health, Cecil K. Calvert, bacteriologist, superintendent of purification, Indianapolis Water Company, Hugh J. Barnhart, director, state department of conservation, and Dr. Thurman B. Rice, Indianapolis, chairman, acting state health commissioner, as ex officio member.

IOWA

Interprofessional Meeting—Miss Stella Scott, R.N., Iowa City, was reelected president of the Iowa Interprofessional Association at its meeting in Des Moines, October 6, and Dr. Alonzo L. Jenks Jr., Des Moines, secretary. Dr. John W. Billingsley, Newton, discussed the Wagner-Murray-Dingell bill and Dr. Walter L. Biering, state health officer, Des Moines, the history of chemotherapy.

State Mental Hygiene Association Proposed—Dr. Norman D. Render, Clarinda, has been named chairman of a committee to develop an Iowa State Mental Hygiene Association. A number of superintendents of state institutions under the state board of control recently met in a preliminary session with Dr. Walter L. Biering, state health officer, to discuss the possibilities of a state society, but final organization will not be effected until spring.

Personal—Howard Reynolds, Ph.D., assistant professor of home economics, University of Arkansas, Fayetteville, has been appointed assistant professor of bacteriology at Iowa State College of Agriculture and Mechanic Arts, Ames, he will also be in charge of research on food bacteriology for the Iowa Agricultural Experiment Station. Lester O. Krampitz, Ph.D., assistant in physiology of the Rockefeller Institute for Medical Research, New York, resigned on September 1 to accept an appointment as research associate at Iowa State College to have charge of the study of penicillin carried out by the Industrial Science Research Institute. —Dr. Frank M. Fuller, Keokuk, since 1925 a member of the Iowa State Board of

Medical Examiners, has resigned. He has been succeeded by Dr. Arthur D. Woods, State Center. Dr. Fuller, a former president of the state medical society, was secretary of the state board from 1925 to 1937.

MARYLAND

Rheumatic Fever and Rheumatic Heart Disease Reportable—On September 23 rheumatic fever was added to the list of reportable diseases by the state department of health. A release from the state department of health states that among children between the ages of 5 and 14 years of age in Maryland rheumatic fever and rheumatic heart disease caused more deaths than any other disease except tuberculosis. The release states further that in the United States in 1941 there were 497 deaths from rheumatic fever between the ages of 5 to 12 and 1,206 deaths in the same age group from tuberculosis. In Maryland for the same year there were 13 deaths in the age group from 5 to 14 from rheumatic fever and 30 deaths from tuberculosis.

Five Year Morbidity Study Ends—The U. S. Public Health Service and the Milbank Memorial Fund have concluded a five year morbidity study in wards 6 and 7 of the Eastern Health District. Miss Jean Downes of the fund supervised the work, which was carried out in cooperation with the Johns Hopkins School of Hygiene and Public Health and the Baltimore Department of Public Health. The chief aims of the study were to ascertain the maximum amount of illness in a population composed of families and to learn more about the chronic diseases which are a major cause of disability. To achieve these aims a responsible member of each family in the study was asked to give information concerning the illnesses in the family to a field worker, who made a visit once a month. Slightly more than 2,000 families participated in the study. The records of sickness, which were collected over a period of five years, are strictly confidential and are to be used for statistical purposes only.

MASSACHUSETTS

License Revoked—The Massachusetts Board of Registration in Medicine revoked the license of Dr. Theodore Rosen, Brookline, October 6, because of "gross misconduct in the practice of his profession as shown by his conviction in court."

Alumni Lecture—Brig. Gen. Raymond W. Bliss, M.C., U. S. Army, assistant to the surgeon general, Washington, D. C., will deliver the Tufts Medical Alumni Lecture, November 17, at the medical school, Boston. His subject will be "Plans and Operations of the Surgeon General's Office."

MICHIGAN

Changes in Health Officers—Dr. Charles F. Atkinson, Indian River, has been appointed medical director of district number 1 of the state health department located at Lake City. —Dr. Albert F. Litzenburger, Boyne City, has been appointed director of district health unit number 3 with headquarters in Charlevoix and serving Charlevoix, Emmet, Antrim and Otsego counties. —Dr. Thomas S. Davies has been named health commissioner of the Grosse Pointe townships, succeeding Dr. Benjamin H. Warren, resigned.

Training Course in Industrial Hygiene for Plant Safety Personnel—The Michigan Industrial Hygiene Society and the School of Public Health of the University of Michigan, Ann Arbor, cooperated in an "in-service training course in industrial hygiene for plant safety personnel," October 19-21. Among the speakers were:

Henry F. Vaughan, Dr. P.H., Ann Arbor, Orientation
Dr. Clarence D. Selby, Detroit, The Significance of Industrial Hygiene
O. F. Lehman, Detroit, The Relationship of the Safety Engineer to Industrial Hygiene
Royd R. Sayers, medical director U. S. Public Health Service, Environmental Aspects of Industrial Hygiene
William G. Frederick, Sc.D., Detroit, Control of Solvent Vapors and Acid Mists
Helmuth H. Schrenk, Ph.D., Pittsburgh, Control of Smokes, Fumes and Gases
J. J. Bloomfield, senior sanitary engineer, U. S. Public Health Service, Evaluation and Control of Dust
W. N. Witheridge, Detroit, Industrial Ventilation Practices
J. A. Purdy, Detroit, Personal Protective Clothing and Equipment
Louis Schwartz, medical director U. S. Public Health Service, Causative Agents of Industrial Dermatitis
Herbert G. Dyktor, Lansing, Plant Sanitation
W. L. Lovett, Detroit, Maintenance and Its Relation to Safety and Health
A. C. Funke, Detroit, How to Make a Survey for Health Hazards
John W. Gibson, Detroit, How to Sell Industrial Hygiene to the Worker
Dr. Kenneth E. Markuson, Lansing, How to Utilize the Resources of Official and Private Industrial Hygiene Agencies

Mental Hygiene Unit for Marquette—The fifth mental hygiene unit to be established under the state's program will be established in Marquette. Recently only two cities submitted bids for this unit, Marquette and Escanaba. (The

JOURNAL, September 18 p 158) The state will submit about \$12,000 in professional salaries to the new child guidance clinic while the host county will be expected to provide about \$3,000 worth of quarters, equipment and secretarial services. All the clinics are organized and supervised by the Michigan State Hospital Commission. Their functions are for the diagnosis and treatment of behavior and personality disorders of children and the promotion of preventive and educational programs.

MINNESOTA

The Bell Lecture—Dr John B. Barnwell, associate professor of internal medicine, University of Michigan Medical School, Ann Arbor, will present the tenth annual John W. Bell Lecture, November 29, Minneapolis, on "Tuberculosis Contacts in Hospital Personnel." The Bell Lecture is sponsored jointly by the Hennepin County Tuberculosis Association and the Hennepin County Medical Society.

MISSOURI

The Barnard Lecture—Clarence C. Little, Sc.D., Bar Harbor, Maine, will deliver the annual Barnard Free Skin and Cancer Hospital Lecture before the St. Louis Medical Society, November 16, on "Influence of Heredity in Human Cancer."

Personal—An honorary degree of doctor of science was given Dr. Joseph Grindon Sr., St. Louis, by St. Louis University at a surprise party in honor of his eighty-fifth birthday on August 20. Dr. Grindon was guest at a dinner given in his honor by the St. Louis Dermatological Society at the Coronado Hotel, St. Louis, August 30. — Dr. Sherwood Moore, director of the Edward Mallinckrodt Institute of Radiology of Washington University, St. Louis, and president of the American Roentgen Ray Society, has been appointed a member of the National Advisory Cancer Council by Surg. Gen. Thomas Parran of the U. S. Public Health Service.

NEW YORK

Graduate Lectures—Dr. Joseph Ernest Del Monaco, associate professor of clinical surgery, Syracuse University College of Medicine, Syracuse, will discuss "Plasma Therapy and Whole Blood Transfusion" before the Tompkins County Medical Society, Ithaca, November 16. Dr. Forrest O. J. Young, associate professor of surgery (plastic surgery), University of Rochester School of Medicine and Dentistry, Rochester, discussed "The Early and Late Treatment of Burns" before the Steuben County Medical Society on November 11 in Bath. The lectures are presented under the joint auspices of the state medical society and the state department of health.

New York City

Mobile X-Ray Unit for Paderewski Hospital—A complete mobile x-ray laboratory is available for eventual use at the Paderewski Polish Hospital, Edinburgh, Scotland. It was developed by the Westinghouse X-Ray Division and purchased by donations from sixty-five American cities.

Division of Industrial Hygiene Created—Dr. Nathan Millman, Brooklyn, has been appointed director of the new division of industrial hygiene established as a joint program of the state department of labor, the New York City Health Department and the U. S. Public Health Service. An experimental program for six months will be carried out in the Astoria Long Island, area.

The Second Harvey Lecture—Francis J. W. Roughton, Ph.D., fellow of Trinity College and lecturer in physicochemical aspects of physiology, Cambridge University, Cambridge, England, will deliver the second Harvey Society Lecture of the current series at the New York Academy of Medicine, November 18. Dr. Roughton's subject will be "Recent Work on the Respiratory Chemistry of the Blood."

Columbia University News—Recent appointments to Columbia University College of Physicians and Surgeons include those of Drs. Conrad Berens as professor of clinical ophthalmology and James M. Smith as professor of clinical otolaryngology. Donald H. Cook, Ph.D., of the School of Tropical Medicine at San Juan, P. R., has been appointed visiting professor of chemistry at Columbia University. The university has received 103 cash gifts totaling more than \$199,000 to finance research in medicine, chemistry and allied sciences as well as to support studies in economics, history, philosophy and statistics. A contribution of \$23,310 from the Commonwealth Fund will be used to finance studies in the department of obstetrics and gynecology.

Personal—Col. George Brehr, chief medical officer, U. S. Office of Civilian Defense, Washington, D. C., and a member of the public health council of the state of New York, has been elected a member of the board of managers of the State Charities Aid Association. — The Bronx Council of the American Jewish Congress has presented Dr. Thomas H. Curtin, president of the Bronx Interfaith Council, with its good citizen award for 1943 in recognition of his efforts toward bringing about "better understanding among men of all faiths." — Dr. Oswald S. Lowsky recently returned from a lecture tour of Central American countries. He conducted conferences and operative clinics in Tegucigalpa, Honduras, San Salvador, Guatemala and Mexico.

Report of Cancer Clinics—Of 654 persons examined in the cancer prevention clinics of Memorial Hospital for the Treatment of Cancer and Allied Diseases during a period of twenty-eight months, 263 came without complaint or symptoms. According to the *Bulletin* of the American Society for the Control of Cancer, 49 were found to have malignant tumors, 162 had benign tumors, 25 had other serious diseases such as heart disease, gastric ulcers and tuberculosis, and 155 were without demonstrable evidence of disease. Of those who applied for examinations, 75 per cent were found to have cancer, the majority having malignant tumors in the early stages. Of the total group who came to the clinic, 29 per cent had benign tumors, 30 per cent had constitutional diseases and 33 per cent showed no disease. Of the 263 who applied but who were unaware of any symptom of disease at the time of their first visit, 4 had malignant tumors, 50 had benign lesions, 15 had some type of serious disease and 194 had no evidence of disease. Revisits to the clinic within a year amounted to 60 per cent. Ten per cent returned in six months.

OHIO

The Lower Lecture—Dr. Irvine H. Page, director, Lilly Clinic, Indianapolis City Hospital, Indianapolis, will deliver the annual Lower Lecture before the Academy of Medicine of Cleveland, November 19. His subject will be "The Nature of Hypertension."

New Health Council—The Columbus Council of Social Agencies has organized a health council to promote the coordination of public and private health work and to aid in securing continuity of program. Under the plan, eight members of the Columbus Academy of Medicine will serve as members of the new health council. Drs. George T. Harding, president of the academy, William D. Inglis, president-elect, George J. Heer, Jonathan Forman, Francis A. Rebel, Clifford C. Sherburne, president, Ohio State Medical Association, Charles W. Pavey and Donald F. Bowers. Dr. Russel G. Means, formerly president of the academy, is chairman of the health council and is one of the eight additional members named by the council of social agencies. Included in the latter group also is Dr. Nelson C. Dysart, health commissioner of Columbus. The combined sixteen members are to select the remaining five persons composing the full membership of the council. Other objectives of the new group are:

To serve as a forum for discussion of health, sickness problems, policies and plans.

To develop new standards of service and to improve present standards through joint study of special problems.

To secure improvement in existing health facilities and services and the establishment of new and additional health facilities or services where needed.

To assist the official and nonofficial agencies in bringing their personnel to a level which meets acceptable standard qualifications.

To cooperate with official and nonofficial health agencies for the provision of refresher courses and in-service training with allocation of time and financial assistance for such purposes if necessary for additional education to meet the standards of national health agencies.

To prevent duplication of effort.

To give moral support to health departments and to aid in community health education in cooperation with the medical and dental societies and other participating agencies.

Society Presents Plan for Obstetric Care of Service Men's Wives—The Montgomery County Medical Society adopted a resolution, October 13, urging the establishment of a private antepartum clinic at the Good Samaritan Miriam Valley and St. Elizabeth hospitals, Dayton, under direct supervision of a staff obstetrician, for wives of enlisted men participating in the Emergency Maternity and Infant Care Program. The resolution declares that the program is placing an added strain on "already overtaxed medical service facilities" in the community and points out that the use of the clinic will in no way interfere with patients employing their own private physicians. Practicing physicians with requisite hospital privileges may refer patients to the private antepartum clinic. They will receive a complete report of the history, physical and laboratory results,

and the referring physician or his associate must be in attendance at the delivery. A list of participating physicians who are approved for obstetric practice in the hospitals shall be available at the city of Dayton and the Montgomery County Health departments. In the event that an applicant for care has no physician, she shall be privileged to select a physician from the prepared list. If no selection is made she shall be referred by the health department to the hospital private antepartum clinic of her choice and the attending staff obstetrician on duty shall make the necessary arrangement for her care. The resolution affirms the agreement of the society with the present purpose of the Emergency Maternity and Infant Care Program namely to offer assistance to the wives and children of boys in the armed forces to record its disagreement with the method of application, viewing with alarm the "spread of bureaucracy in my field."

PENNSYLVANIA

Tuberculosis Fellowships Awarded—The Pennsylvania Tuberculosis Society awarded scholarships to Drs. Philip L. Rettew, Morristown and Thomas G. McQueen, Mifflinsburg. The scholarships will enable the physicians to participate in a postgraduate course in the Trudeau School of Tuberculosis at Saranac Lake, N. Y. Usually only one award is made by the society, but this year two were presented, the Trudeau School made one award available. Dr. Rettew graduated at the University of Pennsylvania School of Medicine, Philadelphia in 1941 and Dr. McQueen at the University of Cincinnati College of Medicine in 1929.

Philadelphia

Ophthalmic Postgraduate Conferences—On November 4 the executive section of the Philadelphia County Medical Society started a series of postgraduate conferences with Drs. Alfred Cowan and Sidney L. Olsho discussing "The Diagnosis of Corneal Diseases" and "Practical Points in the Refraction of the Eye" respectively. Others in the series include:

Drs. Wilfred F. Fry, Pathology and Corneal Diseases, and Isaac S. Friedman, The Newer Techniques in Ocular Refraction, December 16.
 Dr. George F. J. Kelly, Practical Points Pertaining to Perimetry, and Edmund B. Spaeth, Intracocular Foreign Bodies, January 20.
 Drs. Walter I. Lillie, Retrobulbar Neuritis, and James S. Shipman, Rationale of the Use of Sulfur Drugs in Ophthalmology, February 17.
 Drs. Francis H. Adler, Effect of the War Gases on the Eye, and Louis Lehrfeld, Treatment of Glaucoma, March 16.

Annual Dinner of Ex-Resident and Resident Physicians—The fifty-seventh annual dinner of the Association of Ex-Resident and Resident Physicians of the Philadelphia General Hospital will be held on December 7 at the Warwick Hotel with Lieut. Comdr. Thomas F. Duhigg (MC), U. S. Navy, retired, president of the association presiding. Dr. William Pepper, dean of the University of Pennsylvania School of Medicine, will be the guest of honor. Other guests will be Capt. Joseph A. Biello (MC), U. S. Navy, Major Bernard Samuel, Col. Samuel S. Creighton, M. C., U. S. Army, retired, Col. Henry Beckwies, M. C., A. U. S., Capt. Abraham H. Allen (MC), U. S. Navy, Dr. Hubley R. Owen, director of health of the city, Dr. William G. Turnbull, superintendent of the Philadelphia General Hospital, Dr. Herbert M. Goddard, coroner for the county of Philadelphia, and Dr. Frank M. Cline. Ex-residents who do not receive notices of the annual dinner are requested to send their correct addresses to the secretary, Dr. George Wilson, 133 South 36th Street.

County Society Resumes Examinations of Members—The Commission on Physicians' Health, appointed by the Philadelphia County Medical Society in 1941, recently decided to revive its program to hold periodic health examinations of its members. This activity was temporarily discarded in the spring because of the number of physicians of the vicinity who are in the armed forces and because of the death of the chairman of the commission, Dr. James Alexander Clarke Jr. Dr. Myer Solis-Cohen is the new chairman of the commission. *Philadelphia Medicine*, official bulletin of the society, on October 23 carried an announcement outlining the objectives of the program as follows: to preserve the health of each member, to set an example for one's patient and to the public, thereby stimulating periodic physical examinations among them, to find out more about the early beginnings of disease and to prevent illness. Groups of qualified physicians in every branch of medicine will examine members of the society periodically at no expense to those examined, the results to be kept in strict professional confidence. It was pointed out, however, that the investigation will be undertaken only if a sufficient number of physicians register to make it a worthwhile scientific contribution to medical knowledge.

TEXAS

Ordinance Provides Dogs for Baylor University—On September 29 the city council of Houston passed an ordinance "directing that all dogs taken up and impounded and not redeemed or purchased as provided for in said ordinance shall be delivered to the Baylor University College of Medicine, Houston, in such numbers as requested by the college for use in the educational and research program of the college." The action was said to be taken after some opposition had been shown concerning the disposition of these animals to the college of medicine.

WEST VIRGINIA

Refractory Tuberculosis Patients to Be Detained—The Public Health Council of West Virginia at a meeting in Charleston, October 25-27, went on record as defining tuberculosis contagious and subject to quarantine and requested the board of control to take the necessary steps for the detention in the state tuberculosis sanatoriums of "refractory or rebellious patients." It was brought out at the meeting that a number of patients had already left one of the state institutions prematurely, against the advice and without the consent of the members of the staff, to accept work in nearby defense plants. The action was taken by the public health council after the attorney general had ruled such a step legal.

Health Council Reduces Internship—The public health council, cooperating with the federation of state licensing boards, has reduced the period of minimum internship required by license from twelve to nine months. The action was taken at Charleston, October 25-27. The council, in the resolution, declined to accept the recommendation of the council of the West Virginia State Medical Association that temporary permits to practice medicine be granted for the duration to graduates of unrecognized schools in order that medical care might be provided in certain areas where a doctor shortage is found to exist (*THE JOURNAL*, October 23, p. 497). The council felt that the legal difficulties involved would render the successful operation of such a plan impossible. The state medical association recommendation made it clear that such a permit granted would be revoked absolutely not later than six months after the cessation of hostilities. The council will meet in Charleston, January 3-5, to examine applicants for licensure.

PHILIPPINE ISLANDS

Dr. Whitacre Repatriated—Dr. Frank E. Whitacre, professor and head of the department of gynecology and obstetrics at Peiping Union Medical College, Peking, China, is reported to be repatriated on the *Gripsholm* arriving in New York about December 2. Dr. Whitacre has been interned by the Japanese since 1942. He was formerly associated with the Chicago Lying-In Hospital of the University of Chicago and the Tennessee State Medical Association in connection with the Commonwealth Fund postgraduate education program.

GENERAL

Special Society Elections—Dr. Claude W. Munger, medical director of St. Luke's Hospital, New York, was named president-elect of the American College of Hospital Administrators at its meeting in Buffalo in September. Dr. Robert H. Bishop Jr., medical director of the University Hospitals, Cleveland, was installed as president. Dr. John J. Sippy, county health officer, San Joaquin County, Stockton, Calif., was in October named president-elect of the American Public Health Association and Dr. Felix J. Underwood, secretary of the state board of health, Jackson, Miss., was installed as president.

Compulsory Premarital Physical Examinations for Tuberculosis—No states require a premarital physical examination for tuberculosis, according to the *Bulletin of the National Tuberculosis Association*. Three states, Washington, North Carolina and North Dakota, have legislation which prevents persons from marrying who have infectious tuberculosis, and three other states, Delaware, Indiana and Pennsylvania have general laws covering the marriage of persons with a transmissible disease. Tuberculosis is not specified in these laws, it was stated, but would be covered by the term "transmissible disease."

Academy of Tropical Medicine—The American Academy of Tropical Medicine will meet in Cincinnati, November 17, at the Gibson Hotel. Lieut. Col. Thomas T. Mackie, M. C., A. U. S., will act as toastmaster at the association's 10th annual dinner. Dr. Lewis W. Hackett, Buenos Aires, Argentina, will deliver his presidential address on "The South American Scene." Dr. Charles F. Craig, San Antonio, Texas,

be awarded the Theobald Smith Gold Medal of the George Washington University School of Medicine, Washington D C at this session, the presentation to be made by Dr Herbert C Clark, Panama, Republic of Panama

Schering Prizes for Undergraduate Study—"Hormones and Cancer" is the theme of the third nationwide competition for the Schering Award three major prizes of a total value of \$1,000 going to the undergraduate medical students who submit the best critical dissertations on the subject. The Schering Award was established by the Schering Corporation in 1941 for the purpose of encouraging a wider interest in current endocrinologic developments among undergraduate medical students. The competition is sponsored and administered by the Association of Internes and Medical Students, and participation is limited to undergraduate medical students in the United States and Canada. All manuscripts must be submitted not later than Jan 15 1944. Communications should be addressed to "The Interne," 7 East 42d Street, New York 17

Borden Award in Nutrition—The American Institute of Nutrition announces that nominations are now being received for the Borden Award in Nutrition given in recognition of distinctive research by investigators in the United States and Canada, which has emphasized the nutritive significance of the components of milk or of dairy products. The award will be made primarily for the publication of specific papers, but the judges may recommend that it be given for important contributions over an extended period of time. The award may be divided between two or more investigators. Employees of the Borden Company are not eligible for this honor. To be considered for the award, nominations must be in the hands of the chairman of the nominating committee Henry A Mattill, Ph D, University of Iowa, Iowa City, by Feb 1, 1944. The nominations should be accompanied by such data relative to the nominee and his research as will facilitate consideration for the award.

National Malaria Society—The National Malaria Society will meet at the Gibson Hotel, Cincinnati, November 16-18. A joint session of the society with the American Society of Tropical Medicine, Thursday, will consist of a symposium on "A National Program for the Control of Malaria." Included among the speakers on the program will be

Dr Felix J Underwood Jackson Miss, Malaria Prevention Activities of State Boards of Health
Dr Lewis W Hackett Buenos Aires Argentina Spleen Measurement in Malaria and Its Recording
C W Kruse assistant engineer A D Hess malariologist and R L Metcalf assistant entomologist Tennessee Valley Authority, Wilson Dam Ala. Airplane Dusting for the Control of Anopheles Quadrimaculatus on Impounded Waters
James C Andrews Ph D, and William E Cornatzer S M Chapel Hill N C The Absorption of Quinine Salts from Isolated Intestinal Loops of Dogs

Brig Gen James S Simmons M C, U S Army, will deliver his presidential address, Thursday, on "American Mobilization to Combat Wartime Hazards of Malaria"

Society of Tropical Medicine—The American Society of Tropical Medicine will meet in Cincinnati, November 15-18, at the Gibson Hotel. Among the speakers will be

Dr Clarence A Mills and Esther S Cottingham M T Cincinnati, Influence of Vitamin Intake on Phagocytic Activity
Dr Harold W Brown Thomas J Brooks Jr M S and Emanuel Waletzky Ph D Chapel Hill N C The Treatment of Canine Heartworm (Dirofilaria immitis) with Anthiomaline
Dr Henry Hanson Jacksonville Fla Malaria in High Altitudes
Dr Herbert C Clark Panama Republic of Panama The Age Level for the Peak of Acquired Immunity to Malaria as Reflected by Labor Forces
Dr Dimas de Rivas Philadelphia Ambassadors of the Uterus
Drs Ira Muir Clippner and Gordon B Myers Detroit The Protean Manifestations of Weil's Disease

Col George R Callender M C, U S Army, will deliver the eighth Charles Franklin Craig Lecture on Tropical Medicine entitled "Diarrheal Diseases." Dr Noel Paul Hudson, Columbus Ohio will deliver his presidential address on "A Broader Perspective for Bacteriology" at the annual luncheon on Wednesday.

Industrial Hygiene Personnel—On August 4 recommendations concerning the assignment of industrial hygiene personnel were adopted by the sanitary engineering committee which will allow each state with an industrial population of less than 500,000 one industrial hygiene engineer, states with 500,000 or more workers two such engineers and one such industrial hygiene engineer for each additional 500,000 workers. The action stemmed from resolutions presented at the War Conference on Industrial Health in Rochester, N Y, in May, which urged that consideration be given to the present shortage of industrial hygiene personnel. At a meeting in Washington in July J J Bloomfield, senior sanitary engineer, division of industrial hygiene National Institute of Health Bethesda Md, stated that there is a total of 257 professional industrial hygiene

personnel in all of the state and local units of whom 59 are officers on loan from the public health service. The problem of securing engineers and chemists was the major need considered at this meeting since there are only 187 now in service in these units. It was pointed out that the loss of even one man from the division of industrial hygiene in most states would seriously jeopardize the program. Under the new setup the procurement and assignment service for sanitary engineers of the War Manpower Commission will now operate under its new definition of essentiality, so that only those engineers declared available under the new definition of essentiality would be permitted to accept a commission in any one of the services. It is felt that the statistical basis used which allots a certain number of engineers according to the size of the labor force in each state, should work no hardship on any industrial area, with one exception. This exception is the county of St Louis and the committee felt that rather than complicate its new simple definition, and since only one place was involved, it would give favorable consideration to making an exception in the case of St Louis County, allowing the county to have one industrial hygiene engineer in addition to the chief sanitary engineer already allowed under the original ruling. It would seem, therefore that the engineering personnel now operating in the various state and local industrial hygiene units have fair assurance that they will continue at their present posts, at least as far as the industrial hygiene engineering needs of the war agencies are concerned. The army, navy and public health service and maritime commission are at present not recruiting any additional personnel in the field of industrial hygiene engineering, but in the future should any one of these need additional personnel of this type such personnel would have to clear first through the procurement and assignment service for sanitary engineers of the War Manpower Commission.

Nutritional Research Program—The National Live Stock and Meat Board has announced that it will support the following research program for the 1943-1944 period

Dr Paul R Cannon, chairman department of pathology, University of Chicago School of Medicine. The Influence of Dietary Protein on the Regeneration of Blood Proteins and the Resulting Capacity to Fabricate Antibodies
Conrad A Elvehjem Ph D professor of biochemistry, and Frank M Strong Ph D associate professor of biochemistry, University of Wisconsin, Madison. Investigation of the Amino Acid Content of Meats
Dr Elvehjem. The Vitamin Content of Meats and the Nutrition of Vitamins During Cooking
Ruth M Leaverton Ph D associate professor of human nutrition research, University of Nebraska Lincoln, Blood Regeneration in Women Blood Donors
Evelyn G Halliday Ph D associate professor of food and food chemistry and Winifred F Hinman M S instructor in food chemistry, University of Chicago. Retention of B Vitamins in Braising Beef
Sylvia Cover Ph D foods specialist and Paul B Pearson Ph D professor of animal nutrition experimental station, Agricultural and Mechanical College of Texas. College Station. Retention of B Vitamins During the Roasting of Meat
George O Burr Ph D professor and director, division of physiologic chemistry, University of Minnesota Minneapolis. Fat Metabolism and Essential Unsaturated Fatty Acids
Dr Arild E Hansen associate professor of pediatrics, University of Minnesota Medical School Minneapolis. Fat Metabolism in Relation to Human Nutrition
Paul L Day Ph D professor of physiologic chemistry, University of Arkansas School of Medicine Little Rock. Nutritional Cryptopnea and Vitamin M in the Nutrition of the Monkey and Related Studies

Baruch Committee on Physical Medicine—On October 30 the first meeting of the Baruch Committee on Physical Medicine was held in New York. Officers chosen at the session include Dr Ray Lyman Wilbur, chancellor, Stanford University, Calif, chairman, William T Sanger, LL D, president of the Medical College of Virginia, Richmond, vice chairman and Dr Frank H Krusen medical director of the School of Physical Medicine, Mayo Clinic, Rochester, Minn, director-secretary. Other members of the committee are Dr John S Coulter, Chicago Dr Kristian G Hansson, New York, Dr Carl R Comstock, Saratoga Springs, N Y Capt Charles F Behrens (MC), U S Navy, and Lieut Col Benjamin A Strickland Jr, M C, U S Army. Nine special committees and their respective chairmen were appointed as follows

Occupational Therapy Dr Hansson
Polio-myelitis Dr Wilbur
Basic Research Dr Sanger
Clinical Research Dr Coulter
Publicity Dr Wilbur
Hydrology and Health Resorts Dr Comstock
Prevention Dr Hansson
Teaching Dr Krusen
Rehabilitation Captain Behrens

The main office for the Baruch Committee on Physical Medicine will be at 597 Madison Avenue, New York. The activities of the various committees will constitute a survey of the field of physical medicine to determine its potentialities ending it is proposed, in the establishment of a school of physical therapy for its study and teaching (THE JOURNAL November 6 p 648)

Foreign Letters

LONDON

Sept. 25, 1943

The President of the British Medical Association

The vacuum created by the sudden death of Sir Beckwith Whitehouse, president of the British Medical Association, has been filled by the appointment of Lord Dawson, a former president, who held office at the centenary meeting of 1912. This reappointment of a president is unprecedented. Not only is Lord Dawson a leading consultant, but he has an unequalled command of medical politics.

In his address on assuming the presidency of the association Lord Dawson said that in the shaping and organizing of the proposed new medical service doctors must have an important voice. Changes would be deep and fundamental and would affect all members of the profession, no other nation comparably placed had undertaken so big an endeavor. The service must be built in stages. If properly designed, its administrative direction would not interfere with the freedom of the profession, and the minister had promised that the medical profession would have a large share in such administration. He thought that the local administrative body should be a joint board embracing several major local authorities with vocational advisory bodies attached. We wanted the same essential service for all, namely the best, but without dull uniformity. A comprehensive service, free to all citizens, did not necessarily involve a full time salaried service for all doctors, nor was it necessarily incompatible with private practice. Although he believed that more earnings in the future would be derived from salary and less from fees, Lord Dawson said, he was far from convinced that any uniform system of service or payment would meet conditions so multifarious as those attaching to medical practice, and any emergence of official and unofficial groups of doctors would, in his opinion, be disastrous. He recalled one of the evil consequences of the fact that the Ministry of Health did not accept the advice of leaders of the profession in 1929. This was responsible for the existence of two sets of hospitals and two groups of doctors in many towns. If the ministry had accepted the profession's advice and instituted machinery for progressive coordination of local government and voluntary services, we would be much nearer our goal today.

Remarkable Health of British Troops in the War

In his Ludwig Mond lecture at Manchester University Sir Edward Mellanby stated that in this war the health of the British navy, army and air force had been so good as to represent a remarkable achievement. He contrasted this war with Napoleon's invasion of Russia and the French expedition to the Crimea, in which the losses due to illness exceeded those due to wounds and often were more than half the number of soldiers engaged. But even the Eighth Army during its three years in Egypt, Libya and Tunisia, where it has been fighting under conditions ideal for the development of dysentery, typhoid, cholera, smallpox and typhus, has been conspicuously free from disease. Protection by inoculation against typhoid, paratyphoid, cholera, smallpox, tetanus and yellow fever was given to troops before leaving this country. This protection has proved most effective. Much greater protection has been given to our troops by typhoid vaccination than the Italians and Germans have given to theirs. This is reflected in the high rate of these diseases among Italian and German prisoners in our hands as compared to that among our men who were prisoners of the Italians. When the Italian and German prisoners were inoculated with our vaccine, typhoid fever ceased abruptly, and thereafter the endemic rate remained low. Our T A B vaccine

made from strains rich in the Vi antigen proved much more effective than the Italian vaccine made from nonvirulent strains. The Vi antigen was a discovery of a British research worker. The incidence of dysentery, even in the fly swarming western desert, remained relatively low among British troops, and those affected reacted well to recently discovered drugs. The incidence of tetanus among British troops in the Middle East was 0.013 per cent whereas in the South African force, in which active immunization had not been carried out, the incidence was 0.16 per cent—twelve times greater. The incidence of dysentery in the western desert also remained low among British troops and those affected responded well to modern treatment. On the other hand, the incidence among Germans and Italians was much higher. It was said that our success at El Alamein was partly due to the enfeeblement of enemy troops by widespread dysentery. Our success in controlling disease was partly due to recent research, for which our medical scientists have not received due credit.

"The Running Ear" and the Ruptured Drum in the Army

Men with disorders of the ear are so numerous in the army that the *Army Medical Department Bulletin* publishes the recommendation that every case of the sort should be assessed by an otologist, so that the medical officer may know its exact nature and appropriate treatment. Otologists are requested to classify chronic otitis media as active, quiescent or healed. Broadly speaking, patients with active otitis media need treatment and are fit only for home service, quiescent otitis media needs prophylactic measures and these patients should usually be placed in category B or C. Healed otitis media should be categorized according to the standard of healing. The vast majority of soldiers with discharging ears can be suitably employed in the army. Meticulous cleansing of the external auditory meatus is important. As a rule the ears are best kept dry by insufflation of boric acid and iodine or sulfonamide powder.

Every medical officer should know how to prevent infection of the middle ear when the drum is ruptured. A high proportion (50 per cent) of those injured by blast sustain rupture of the drum. In many this is overlooked because of absence of symptoms or because of more serious wounds. If there is the least chance that the drum has been injured, no drops of any description should be permitted to enter the ear, and on no account should the ear be washed out with a syringe. No manipulations, except under complete asepsis, should be made in the meatus, which must be protected by a sterile dressing of cotton wool. The patient should be told not to blow his nose. If infection of the ear is anticipated, the prophylactic sulfonamide should be given by mouth, and the patient should be seen by the otologist.

Marriages

- PAUL CALVIN JENKS, Burlington, Vt., to Miss Patricia Bickelhaupt of Hammond, N. Y., in New York, September 25.
NATHANIEL ROSCOE SPENCER, Washington, D. C., to Miss Barrier Mae Walsworth of Monroe, La., October 23.
NORMAN W. RAUSCH, Orange, N. J., to Miss Adele D. Hinklemann of West Hartford, Conn., in August.
RUFUS HENRY ALIDREDGE, New Orleans, to Miss Mary Elizabeth Barrett at Hammond, La., October 30.
BENJAMIN FRANKLIN LEVY to Miss Joyce Ann Cantor, both of Syracuse, N. Y., in Ithaca, September 18.
GEORGE WILLCOX BROWN, Marietta, Ga., to Miss Betty Andrews of Augusta, September 4.
WARREN FRANCIS SMITH, Oak Park, Ill., to Miss Barbara O'Malley of Chicago recently.
HERMAN GLADSTONE, Chicago, to Miss Madge Willstaetter " New York, October 17.

Deaths

Wright Clarkson of Petersburg, Va., Medical College of Virginia, Richmond, 1912, Army Medical School 1918, specialist certified by the American Board of Radiology, Inc., member of the House of Delegates of the American Medical Association 1935, 1936, 1938, 1939 and 1940 member of the American Roentgen Ray Society, Radiological Society of North America, Inc., American College of Radiology, American Radium Society, Southern Medical Association, and the Petersburg Medical Faculty, past president of the American Association for the Study of Neoplastic Diseases, a founder and president of the Virginia Radiological Society served as vice president of the Tri-State Medical Association of the Carolinas and Virginia a founder of the Fourth District Medical Society and chairman of its steering committee served in the medical corps of the U S Army during World War I in 1920 chief of x-ray service at the General Hospital number 41, New York, a lieutenant commander in the medical corps U S Naval Reserve, on the staffs of the John Randolph Hospital Hopewell, Petersburg and Central State hospitals, founder and president of the Virginia Cancer Foundation, trustee of the Southern College, radiology editor, *Southern Medicine and Surgery*, died in the Garfield Memorial Hospital, Washington, D C, October 17, aged 53, of leukemia.

Frank William Howard Taylor, Los Angeles, College of Physicians and Surgeons, Los Angeles, 1917, also a lawyer, member of the California Medical Association, instructor in x-ray and electrotherapy at the University of Southern California, 1919-1920, instructor in military x-ray and chief roentgenologist, medical corps, U S Army, and later lieutenant commander in the U S Naval Reserve during World War I roentgenologist at the Clara Barton, French, Angelus and Roosevelt hospitals, Pottenger Sanitarium and the Veterans Administration Facility Sawtelle from 1919 to 1929, vice president of the Taylor Holding and Investment Corporation, medical consultant and medical director of the Southwest X-Ray and Clinical Laboratories author of "Lawyers' Text and Atlas of the Human Body" died July 2, aged 52, of coronary thrombosis.

Wilson Johnston of Portland, Ore., Kentucky School of Medicine Louisville 1892 associate clinical professor of ophthalmology at the University of Oregon Medical School, specialist certified by the American Board of Ophthalmology and the American Board of Otolaryngology member of the House of Delegates of the American Medical Association in 1911, member of the American Academy of Ophthalmology and Otolaryngology Western Ophthalmological Society and the Pacific Coast Oto-Ophthalmological Society past president of the Oregon and Washington state medical societies formerly a member of the Washington State Board of Health fellow of the American College of Surgeons served during World War I, chairman for the procurement and assignment service, on the staff of the Coffey Memorial Hospital, died in Multnomah August 15 aged 75, of coronary thrombosis.

Robert Jesse Reynolds, Potsdam, N Y., Columbia University College of Physicians and Surgeons, New York, 1915, member of the Medical Society of the State of New York, secretary of St Lawrence County Medical Society, served on the Mexican border in 1916 and as a captain in the medical corps of the 27th division in France during World War I, member and examining physician for draft board number 412 secretary of the staff of the Potsdam Hospital on the staff of the Stephen B Van Duzee Hospital Gouverneur, and the Massena Memorial Hospital a director of the Citizens National Bank and emergency medical director of St Lawrence County War Council died in Madrid August 14 aged 52, of coronary thrombosis.

Edgar Cannon Armstrong, Laurel Miss., University of Nashville (Tenn.) Medical Department 1908 member of the Mississippi State Medical Association died August 29, aged 61.

John T Bogard, Mena Ark. Memphis (Tenn.) Hospital Medical College 1899 died August 20, aged 72.

Charles William Bower, Lehighton, Pa. University of Vermont College of Medicine Burlington 1879 University of Pennsylvania Department of Medicine, Philadelphia, 1880 died August 29 aged 88 of senility.

Charles F Brady, Parsons Kan. Keokuk (Iowa) Medical College College of Physicians and Surgeons, 1903 died August 13 aged 65 of coronary occlusion.

Charles E Caswell, Wichita Kan. Kansas Medical College Medical Department of Washburn College, Topeka, 1902,

member of the Kansas Medical Society, died recently, aged 73 of cerebral thrombosis and arteriosclerosis.

Frederick J Champney, North Baltimore, Ohio, Detroit College of Medicine, 1893, died in Findlay August 17, aged 76 of pneumonia.

William H Chapman of Blythe, Calif., University of Nebraska College of Medicine Omaha, 1902, member of the city council, school board and chamber of commerce physician for Riverside County and the Santa Fe Railroad, died in the Loma Linda Sanitarium and Hospital August 19, aged 66, of bronchopneumonia and hypertension.

Stephen Reaves Coleman, Washington D C. University of Texas School of Medicine Galveston 1917, on Sept 7, 1942 commissioned a major in the medical corps, Army of the United States, not on active duty served during World War I associated with the Veterans Administration on the staff of the Veterans Administration Facility, past president of the District of Columbia Urological Society, died August 30, aged 55, of hypertension.

Louis Joseph Cooke, Minneapolis, University of Vermont College of Medicine Burlington, 1894, director of athletics at the University of Minnesota, formerly physical director of the Y M C A at Toledo, Ohio, Duluth, Burlington, Vt., and Minneapolis, on the staff of the University Hospitals, died August 19, aged 75, of hypertension.

Willis Hiram Corson, Seattle, Cooper Medical College San Francisco, 1905 member of the Washington State Medical Association, served with the Italian army during World War I awarded the Italian Cross of Honor and a Chevalier of the Crown in recognition of exceptional service to the Italian people, formerly coroner of King County, at one time medical superintendent of the King County Hospital, died August 19, aged 64, of carcinoma of the larynx.

Robert Duval Cousins, Beaumont, Texas, Fort Worth School of Medicine, Medical Department of Fort Worth University, 1902 died August 26, aged 68, of typhus and pneumonia.

Omar Legrand Cox of Iola, Kan., Cotner University Medical Department, Lincoln, Neb., 1894, secretary and past president of the Allen County Medical Society, a captain in the medical corps of the U S Army during World War I, member of the State Board of Medical Registration and Examination, on the staff of St John's Hospital, died in the Veterans Administration Facility, Wichita, August 22, aged 76, of heart disease.

Mary Gamble Cummins, Oak Bluffs, Mass. the Hahnemann Medical College and Hospital, Chicago, 1893, at one time a member of the board of education of Paterson, N J died August 20, aged 73.

Emory S Deaver, Monroe Ga. Hospital Medical College, Atlanta, 1911, died August 25, aged 65, of heart disease.

William Emmett Denman, Greenwood, Miss. Memphis (Tenn.) Hospital Medical College, 1907, member of the Mississippi State Medical Association and the American College of Chest Physicians, on the staff of the Greenwood-Lefflore Hospital, died August 28, aged 61, of coronary occlusion.

Edwin Strassbridge English, Brevard, N C., University of the South Medical Department, Sewanee, Tenn. 1900 past president of the Transylvania County Medical Society member of the Medical Society of the State of North Carolina on the staff of the Transylvania Community Hospital, died August 19, aged 75, of coronary thrombosis.

Charles Henry Gardner of Senior Surgeon, U S Public Health Service, retired, Baltimore. Columbian University Medical Department, Washington, D C., 1890 entered the U S Public Health Service on Jan 28, 1892, died in the U S Marine Hospital August 10, aged 78, of coronary thrombosis.

Eugene John Gay, French Camp Calif., Drake University Medical Department, Des Moines, 1897, member of the California Medical Association on the staff of the San Joaquin General Hospital where he died recently aged 72 of rheumatic heart disease.

David Arnold Goldman, St Louis. St Louis University School of Medicine, 1935 member of the Medical Association of Georgia, began extended active duty as a first lieutenant in the medical reserve corps of the U S Army on Nov 5, 1940, honorably discharged Aug 17 1941 died in the Frisco Employees' Hospital August 25, aged 35, of multiple polyposis carcinoma.

Frank Starr Gregory of Redwood City, Calif., Cooper Medical College, San Francisco, 1900, past president of the San Mateo County Medical Society, head of the Selective

Service Board at one time mayor of Pittsburg, on the staff of the Mills Memorial Hospital San Mateo, where he died August 21, aged 68, of myocardial infarction

Paul Lee Hammond, Bradley Ark St Louis College of Physicians and Surgeons 1917, Kansas City (Mo) College of Medicine and Surgery 1921 died August 6, aged 53

John Windsor Harbarger, Jackson Ohio Kentucky School of Medicine Louisville 1892 a captain in the medical corps of the U S Army during World War I died in the Veterans Administration Facility, Huntington, W Va, August 27, aged 76 of heart disease

Henry Winston Harper & Austin Texas University of Virginia Department of Medicine Charlottesville 1892 also a pharmacist and lawyer teacher of chemistry at the University of Texas from 1894 to 1943 and dean of the graduate school from 1915 to 1935 died in the Seton Hospital August 28, aged 84

Charles Lewis Haywood Jr & Elkin N C Harvard Medical School, Boston 1927, diplomate of the National Board of Medical Examiners fellow of the American College of Surgeons medical director of the Hugh Chatham Memorial Hospital, died August 22 aged 40 of coronary thrombosis

Joseph Marion Heard, Aberdeen, Miss Long Island College Hospital Brooklyn 1890, died August 25, aged 89, of intestinal hemorrhage

Frederick Eric Hellbaum, Bakersfield Calif, Stanford University School of Medicine, San Francisco, 1935, commissioned a captain in the medical corps Army of the United States Sept 2 1942 and honorably discharged Jan 16 1943, served as resident physician at the Kern General Hospital, on the staff of the Mercy Hospital, where he died September 4, aged 41 of coronary occlusion

Robert Wing Hemingway & Bend Ore, Rush Medical College Chicago, 1925, also a pharmacist, fellow of the American College of Surgeons, member of the staffs of St Charles and Lumbermen's hospitals, died August 27, aged 48, of coronary thrombosis

Archibald Murphy Henry, Brownwood, Texas, Louisville (Ky) Medical College, 1888, died July 1, aged 82

Melvin K Henry & Philadelphia, University of Pennsylvania Department of Medicine Philadelphia, 1893, formerly on the staff of the Frankford Hospital, died August 5, aged 72, of bronchial asthma and coronary thrombosis

Wallace John Herriman, Rochester, N Y University of the City of New York Medical Department, 1879, served as a surgeon, lieutenant commander in the U S Navy during World War I, died August 28 aged 85

Albert James Hodgson, Waukesha Wis, Rush Medical College, Chicago, 1886, member of the State Medical Society of Wisconsin, formerly secretary of the Waukesha County Medical Society awarded an honorary degree of doctor of science by Carroll College in 1916, died in the Summit Hospital, Oconomowoc, Wis, October 5, aged 84, of myocarditis

Frederick F Holroyd, Princeton, W Va, College of Physicians and Surgeons Baltimore, 1910, member of the West Virginia State Medical Association served during World War I, city health officer, chief physician for the Mercer County Jail, on the staff of the Mercer Memorial Hospital, died August 15, aged 57, of coronary thrombosis

Jerry Morris Hyde & Nelsonville, Ohio, Bellevue Hospital Medical College, New York, 1885, formerly examiner for several insurance companies, died August 26, aged 83, of cerebral hemorrhage

George Tasker Imrie & Rochester, N Y, Trinity Medical College, Toronto, Ont, Canada, 1902, member of the staff of the Park Avenue Hospital, died August 28, aged 71, of cerebral hemorrhage

Oscar Lee Jones, Fort Worth, Texas, University of Louisville (Ky) Medical Department, 1887, died in the Methodist Hospital August 21, aged 79, of heart disease

Charles Wesley Larkins, Cincinnati, Eclectic Medical College, Cincinnati, 1918, advisory member of Selective Service Board number 29, Westwood, past president of the Westwood Athletic Club, died in the Bethesda Hospital August 28, aged 54, of hypertension

Charles Buchanan Law, Mineral Wells, Texas, Memphis (Tenn) Hospital Medical College, 1913, served during World War I, died in the Nazareth Hospital August 24, aged 59, of coronary disease

Charles Leali, Kingsland, Ark, Missouri Medical College, St Louis, 1882, died July 29, aged 84

Harry Hamilton Lewis, Louisville, Ky, University of Louisville Medical Department, 1890, died August 7, aged 75, of carcinoma and arteriosclerosis

Charles Day Lipscomb, Quitman, Texas, Medical Department of Tulane University of Louisiana, New Orleans, 1902, served as health officer of Wood County, died in August, aged 77

Clifford Athenus Lutgen & Auburn, Neb, Lincoln Medical College of Cotner University, 1901, president of the Nemaha County Medical Society in 1936, president of the Nebraska Hospital Association in 1940, for many years a member of the city library board, member of the chamber of commerce, past president and charter member of the Auburn Kiwanis Club, medical director and owner of the Auburn Hospital, died August 15, aged 70, of virus pneumonia

Will R McCamy, Knoxville, Tenn, Chattanooga Medical College, 1901, member of the Tennessee State Medical Association, died August 6, aged 66, of pneumonia

Joseph Hamilton McLeskey, Charlotte, N C, University of Georgia Medical Department, Augusta, 1909, member of the Medical Society of the State of North Carolina, on the staffs of the Mercy and Presbyterian hospitals, died in Clemson College, S C, August 4, aged 59 of coronary thrombosis

Frederick Henry Martin, Libertyville, Ill, the Hahnemann Medical College and Hospital, Chicago, 1899, a captain in the medical corps of the U S Army during World War I, died in the Veterans Administration Facility, Downey, August 18, aged 71, of chronic myocarditis and arteriosclerosis

Paul Dickinson Maxwell, Utica, N Y, Syracuse University College of Medicine, 1938, member of the Medical Society of the State of New York, on the staff of the Rome State Hospital, died August 21, aged 31, of cerebral thrombosis

Arthur S Monzingo & Gig Harbor, Wash, Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1905, superintendent and owner of the Gig Harbor Hospital, where he died August 21, aged 66, of coronary thrombosis

Charles Emory Morse & La Junta, Colo, Denver and Gross College of Medicine, 1909, president of the staff of Menomite Hospital, died August 16, aged 63, of coronary thrombosis

Edwin Smith Moss, Williamsburg, Ky, Hospital College of Medicine, Louisville, 1881 member of the Kentucky State Medical Association president of the First National Bank for thirty-five years, for fifty years served as medical referee for Whitley County, chairman of the county board of health, for many years local surgeon for the Louisville and Nashville Railroad, died August 23, aged 83, of senility

John J Moylan, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia, 1882, for many years chief of staff of St Mary's Hospital on the staffs of the Germantown Dispensary and Hospital and St Joseph's Hospital, attending physician at the Little Sisters of the Poor Home for the Aged and the House of Good Shepherd, died August 2, aged 85

Ralph Lyle Oppen, O'Neill, Neb, University of Nebraska College of Medicine, Omaha, 1940, appointed a first lieutenant in the medical corps of the National Guard on Dec 23, 1940, assigned to the medical detachment, 134th Infantry, Camp Joseph T Robinson, Arkansas, on Feb 1, 1942 appointed a captain in the medical corps, Army of the United States, honorably discharged, May 5, 1943 because of physical disqualification, died August 6, aged 33, of cardiac decompensation

John Thomas Pattison, Langley, S C, University of Georgia Medical Department, Augusta, 1890, died in a hospital at Anderson August 19, aged 73

Charles Elvie Peel, Watseka Ill, Barnes Medical College, St Louis, 1906, formerly physician for the Illinois Central Railroad, died August 25, aged 74, of coronary thrombosis and bronchial asthma

William Waldo Rambo & Jefferson City, Mo Washington University School of Medicine, St Louis, 1926 for many years physician and surgeon for the Missouri State Penitentiary, died August 9, aged 50, of cerebral hemorrhage

George Lawrence Ramsey, Powhattan Point Ohio Ohio Medical University, Columbus, 1898 member of the Ohio State Medical Association, for many years president of the board of education, died in the City Hospital, Bellaire, August 29, aged 71

Edgar Thomas Ray, New York, Columbia University College of Physicians and Surgeons, New York, 1906 chief medical officer of the city of New York fire department during World War I, died in Brooklyn August 27, aged 71

Matthew Simpson Reay, Randolph, Utah College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1903 member of the Utah State Medical Association, member of the county Selective Service Board during World War I and II died in the Caribou County Hospital, Soda Springs, Idaho, August 6, aged 63

Edward Clifton Rinehart & Struthers, Ohio, Ohio State University College of Medicine, Columbus 1913, died in the Youngstown Hospital, North Side Unit, August 29, aged 56, of heart disease

Isaac Burton Roberts, Limerick Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1897, member of the Medical Society of the State of Pennsylvania, served overseas during World War I, school doctor in Haverford township for many years and adviser to the board of health, member of the staff of the Delaware County Hospital, Drexel Hill, where he died August 29 aged 68 of injuries received when the automobile in which he was driving was struck by a trolley car

John William Rockefeller, Loch Arbour, N J., College of Physicians and Surgeons, New York, 1890 died August 22, aged 73, of chronic myocarditis and intestinal neoplasm

Holbert A. Rogers, Jeffersonville, Ga Atlanta College of Physicians and Surgeons, 1909 died in the State Tuberculosis Sanatorium Alto, August 7, aged 59, of tuberculosis

Melville Erskine Rumwell, Palo Alto, Calif., Cooper Medical College, San Francisco, 1895 formerly associate clinical professor of surgery at the Stanford University School of Medicine one of the first appointees on the board of the state industrial accident commission and for many years served with the state compensation insurance fund, formerly visiting physician at the Crocker Home and medical director of the Olympic Club died August 3 aged 70

Charles T Schrader, Bristow, Okla., Hospital College of Medicine, Louisville, Ky, 1905, member of the Oklahoma State Medical Association mayor of Bristow for three terms, on the staff of the Cowart-Sisler Hospital died August 27, aged 64 of angina pectoris

Edwin Forrest Sibley & Kingston, N Y Albany Medical College 1903, served in the medical corps of the U S Army during World War I on the staffs of Benedictine Hospital and the Kingston Hospital died in the Albany Hospital August 24, aged 64 of general arteriosclerosis and coronary sclerosis

Hans Eugen Simmel, Warren, Ohio, Friedrich-Wilhelms-Universität Medizinische Fakultät Berlin, Prussia, Germany, 1914 on the staff of the Warren City Hospital, died in Colorado Springs, Colo., August 23 aged 52, of peritonitis

Emery Singer, Avenel, N J University of Kolozsvár, Hungary 1911 died in the General Hospital, Perth Amboy August 23 aged 57 of coronary thrombosis

R B Slater, Craig Colo St Louis College of Physicians and Surgeons 1921, also a pharmacist secretary of the school board, on the staff of the Solandt Memorial Hospital Hayden died in Jackson Wyo August 13, aged 52, of coronary thrombosis

Harry Wilbur Smith, Norridgewock, Maine Dartmouth Medical School, Hanover, N H, 1900 member of the Maine Medical Association school physician library trustee, a member of the town advisory committee, on the staff of the Redington Memorial Hospital Skowhegan died August 19, aged 73 of cerebral hemorrhage

Francis George Speidel & Washington D C, George Washington University School of Medicine Washington 1917 served in the U S Navy during World War I member of the staffs of the George Washington University Doctors Eastern Dispensary and Casualty Childrens and the Central Dispensary and Emergency hospitals died in Richmond, Va., August 30 aged 51 of acute myocarditis

Sam Houston Spruwell, Gouldbusk, Texas, University of Texas School of Medicine Galveston 1907 died August 27, aged 66 of chronic myocarditis and chronic nephritis

Zella White Stewart, Iowa City, Cornell University Medical College New York 1904 member of the American Association for the Study of Allergy died August 4, aged 65 of cerebral hemorrhage and hypertension

Alexander Williamson Stirling, Baldwin, Ga., M.B. University of Edinburgh Faculty of Medicine Scotland 1880 and M.D. in 1887, member of the Medical Association of Georgia fellow of the American College of Surgeons formerly on the staffs of the Wesley Memorial Hospital Presbyterian Hospital and Tabernacle Infirmary Atlanta died August 16 aged 85

Bernhardt Kurt Stumberg, St Charles, Mo Maryland Medical College, Baltimore 1900 member of the Missouri

State Medical Association, veteran of the Spanish American War and World War I, on the staff of St Joseph's Hospital medical director of the Lindenwood College, died August 20 aged 67, of coronary occlusion

John Samuel Talley, Frouthman N C University of North Carolina School of Medicine, Raleigh 1909 member of the Medical Society of the State of North Carolina past president and vice president of the Irdeell Alexander Counties Medical Society, died in the Davis Hospital, Statesville, August 4, aged 63, of coronary occlusion

Daniel Herman Tellman & Passaic N J Columbia University College of Physicians and Surgeons New York, 1923 on the staff of the Beth Israel Hospital died in the Memorial Hospital for the Treatment of Cancer and Allied Diseases New York, August 26, aged 41, of acute leukemia

Albert S Thompson & Mount Horeb Wis., Minneapolis College of Physicians and Surgeons, 1902 for many years local health officer died in the Methodist Hospital, Madison August 28, aged 65, of coronary thrombosis

Charles Urban Thralls, Hymery, Ind., Illinois Medical College, Chicago, 1903, member of the Indiana State Medical Association on the staff of St Anthony's Hospital, Terre Haute, died August 23, aged 64 of Hodgkin's disease

Richard E Timberlake, Youngsville, N C Jefferson Medical College of Philadelphia, 1908, examiner for several insurance companies, died August 10, aged 64 of cerebral hemorrhage

William S Tyson, New Boston, Texas University of Nashville (Tenn.) Medical Department, 1908 for several terms served as health officer of Bowie County, died recently, aged 57, of heart disease

George King Wassell, Dallas, Texas, Northwestern University Medical School, Chicago, 1935, member of the State Medical Association of Texas instructor in surgery at the University of Michigan Medical School, Ann Arbor, from 1936 to 1938, assistant in clinical surgery at Baylor University College of Medicine from 1938 to 1943, assistant in clinical surgery at the Southwestern Medical Foundation School of Medicine dispensary surgeon, Baylor Hospital, died August 31, aged 33, of heart disease

Walter Walton Watson, Philadelphia, Medico-Chirurgical College of Philadelphia 1900, member of the Medical Society of the State of Pennsylvania, died August 13, aged 69

Moses Weiss, New York, Deutsche Universität Medizinische Fakultät Prague, Czechoslovakia, 1927, member of the Medical Society of the State of New York formerly president of the Balneological Society of Saratoga Springs died in the New England Baptist Hospital, Boston, August 8, aged 41, of recurrent carcinoma of the cecum with generalized metastases

Arthur Henry Wilson, Indianapolis Indiana Medical College School of Medicine of Purdue University, Indianapolis, 1907, served with the American Expeditionary Forces during World War I lieutenant colonel in the medical reserve corps of the U S Army not on active duty, died August 3, aged 67, of hypertension

James T Windell, Louisville, Ky., University of Louisville Medical Department 1892 member of the American Urological Association, died August 8, aged 78, of carcinoma

DIED WHILE IN MILITARY SERVICE

Robert Carl Badertscher, Bloomington Ind Indiana University School of Medicine, Indianapolis, 1940 member of the Indiana State Medical Association, commissioned a first lieutenant in the medical reserve corps of the U S Army on June 30 1940 beginning extended active duty on July 2 1941 commissioned a captain flight surgeon with the second photographic charting squadron died at Iquitos, Peru, in an airplane crash September 6 aged 27

Eugene Winston Matlock & Port Arthur Texas University of Texas School of Medicine Galveston 1922, past president of the Jefferson County Medical Society fellow of the American College of Surgeons member of the surgical staff at St Mary's Hospital, began extended active duty as a lieutenant commander in the medical corps of the U S Naval Reserve Sept 7, 1942 formerly stationed at the U S Naval Hospital at Corpus Christi and the U S Naval Training School at Norman Okla died in an airplane crash near Madisonville Feb 16 1943, aged 43

Correspondence

UNILATERAL NEPHRECTOMY AND HYPERTENSION

To the Editor—In THE JOURNAL, October 2, page 277, Weiss and Chasis rightfully infer from the failure of the removal of a chronic atrophic pyelonephritic kidney to lower the blood pressure of a patient with hypertension that the diseased kidney probably was not causally related to the hypertension. From the fact that the other kidney showed normal blood flow, glomerular filtration rate and maximal tubular excretory capacity, however, they conclude that the remaining kidney was not diseased or ischemic and therefore not responsible for the hypertension. That the remaining kidney was not ischemic is obvious but that it "cannot be indicted for this failure [of the nephrectomy to reduce the blood pressure in the patient] is not necessarily true.

The mechanism whereby constriction of the renal artery produces hypertension in experimental animals is still unsettled. Although a reduction in pulse pressure may be involved (Kohlstadt, K. G. and Page, I. H. Liberation of Renin by Perfusion of Kidneys Following Reduction of Pulse Pressure, *J. Labor Med* 72:201 [Aug] 1940), local renin appears not to be (Marionfeld, C. J., and Wakerlin, G. E. The Effect of Sodium Cyanide on the Formation of the Pressor Substance of the Completely Ischemic Kidney, *Fed Proc* 2:32 [March 16] 1943). The evidence for increased liberation of renin into the circulation is suggestive but inconclusive (Page, I. H. Demonstration of the Liberation of Renin Into the Blood Stream from Kidneys of Animals Made Hypertensive by Cellophane Perinephritis, *Am J Physiol* 130:22 [July] 1940. Dell'oro, R., and Braun-Menendez, E. Dosaje de renina en la sangre de perros hipertensos por isquemia renal, *Rev Soc argent de biol* 18:65 [May] 1942), and the opposite view of a reduction in a postulated normal antipressor activity of the kidney has recently been stressed (Grollman, Arthur, and Rule, Colter. Experimentally Induced Hypertension in Parahibiotic Rats *Am J Physiol* 138:537 [March] 1943. Grollman, Arthur, Harrison, T. R., and Williams, J. R., Jr. Experimental Renal Hypertension in the Rat, *ibid* 139:293 [June] 1943). In any event renal ischemia is not necessary, as was formerly thought. Thus there is excellent evidence that experimental renal hypertension can occur with normal renal blood flow, glomerular filtration and maximal tubular excretory capacity (Corcoran, A. C., and Page, I. H. Renal Blood Flow in Experimental Renal Hypertension, *Am J Physiol* 135:361 [Jan] 1942).

Moreover, recently moderate hypertension developed in 4 of our dogs following bilateral constriction of the renal arteries (Wakerlin, G. E., Moss, W. G., and Goldberg, M. L. Unpublished observations). Six to twelve months later one kidney was of normal or near normal size whereas the other was approximately two-thirds normal size. On the theory that the normal sized kidney was not contributing to the hypertension and possibly even exerting an antihypertensive effect, the larger kidney was removed in an effort to obtain a more pronounced hypertension. In each dog the blood pressure fell to a persistent near normotensive level. Other observations in our laboratory also point to the probability that a kidney which is rendered ischemic by renal artery constriction is less effective in producing a high level of chronic or benign (in contrast to malignant) experimental hypertension than one which maintains a normal or near normal blood flow after constriction.

The fact that unilateral nephrectomy has been successful in reducing the elevated blood pressure to normal in only 7 of 76 patients as quoted by Weiss and Chasis is not evidence against the possible involvement of the kidney directly or indirectly in the pathogenesis of essential hypertension but rather against the premature and sometimes misinterpreted application of incomplete laboratory results to pressing clinical problems. On the other hand, the numerous similarities between essential hypertension and experimental renal hypertension do not prove even a partial common pathogenesis. Only future work can determine whether essential hypertension is a generic classification, one group of which may be of renal origin.

Consequently, although the hypertension in the case reported by Weiss and Chasis may well not be on a renal basis, this possibility is not ruled out when the evidence presented is viewed in the light of recent experimental findings.

DIPHTHERIA MORTALITY—TYPHOID CARRIERS—POLIOMYELITIS IN PREGNANCY

To the Editor—This is to commend you on the excellent editorial on "Diphtheria Mortality in the United States."

You call attention to the fact that Dr. J. C. Geiger of San Francisco has noticed a recent increase in deaths from diphtheria in older age groups. I thought you would be interested to know that during this year, to date, out of seven deaths from diphtheria in Los Angeles five were of persons over 40 years of age. As there were 13 patients over 40 years of age this makes a specific mortality rate of 38 per cent. During 1942 there were 27 patients over 40 years of age with diphtheria and seven deaths, or a specific mortality rate of 26 per cent. It would seem that diphtheria is being overlooked in the older age groups.

It may also interest you to know that 9 of the last 10 typhoid carriers discovered by our investigator are grandmothers.

It is noted in the September 25 issue of THE JOURNAL that Drs. Harmon and Hoyne reported 2 cases of poliomyelitis complicating pregnancy. It is interesting that the symptoms given in both of these cases point to bulbar poliomyelitis. Of 4 pregnant women admitted to the Los Angeles County General Hospital with poliomyelitis during the last few months, 3 had bulbar poliomyelitis, 2 of whom died. Both of the latter 2 delivered normal children before they died.

GEORGE M. UHL, M.D. Los Angeles
Health Officer

VINCENT'S ANGINA OF THE TONSIL

To the Editor—In reference to a report (THE JOURNAL October 9, p. 341) titled "Treatment of Vincent's Angina of the Tonsil," Major C. S. Linton treats the gingival margins in the following manner: "When infection also was present about the gum margins, it was advised that the sulfathiazole tablet be moistened with a few drops of water to make a paste and this used to rub into the gum margins." In this preliminary report it is stated that the author in his search of the literature failed to find any use of sulfonamide drugs for this purpose. He also indicates that Spink in his book reports that sulfanilamides have been used in the treatment of Vincent's angina with no benefit from local administration.

May I call to your attention the fact that I reported beneficial results in June 1942 (Sulfa Drugs in Local Treatment of Necrotic Gingivitis [Vincent's infection] *New York Journal of Dentistry* 12 251 [June] 1942) I also reported them in Miller's Textbook of Periodontia (ed 2, Philadelphia Blakiston Company, 1943, chapter XVII) In both of these publications I indicated the use of a sulfonamide paste

STERNAL TRANSFUSIONS IN BURNS

To the Editor—This communication is prompted by a quotation printed on page 815 of the July 17 issue of THE JOURNAL. The quotation is taken from a pamphlet entitled "Treatment of Burns and Prevention of Wound Infections, published by the Medical Division of the Office of Civilian Defense. In a discussion of the technique of administering plasma we are told that "it must never be administered by any other than the intravenous route."

The published reports on infusions via the bone marrow of Tocantins and O'Neill (THE JOURNAL Oct 11 1941) and of Doud (*ibid*, Dec 12, 1942) testify to the feasibility of the bone marrow route for infusions of blood plasma, dextrose or saline

Administration of plasma through infusion needle into bone marrow of sternum

solution. This point bears emphasis because it is in just such cases of severe burns that superficial veins are apt to be either completely collapsed or involved in the burned area. Sternal bone marrow infusion presents an alternative route for fluid therapy. Plasma in such instances is life saving, and in that marrow infusion makes it available marrow infusion is life saving.

The procedure of sternal marrow infusion seems to be little known. Experience with it in war casualties has demonstrated its value and simplicity. The pamphlet quoted emphasizes the need for a rapid flow of a plasma infusion on occasion. A sternal infusion flows at a rate comparable to an intravenous infusion. The accompanying photograph illustrates our use of the procedure during the recent New Georgia campaign. The patient is a wounded Japanese prisoner.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts Right of Osteopath to Perform Minor Surgery—Thierfelder, who was licensed to practice osteopathy in Montana, was charged in a criminal information with practicing medicine without a license in that on a stated day he performed a tonsillectomy on a stated patient. The trial court held, apparently, that the osteopath was not guilty of practicing medicine without a license, since a licensed osteopath could legally perform a tonsillectomy in Montana, and directed the jury to return a verdict in the osteopath's favor. The state then appealed to the Supreme Court of Montana.

A section of the Montana osteopathic practice act enacted in 1901 (Laws 1901, p. 50 sec. 6) read, in part, as follows:

"The certificate provided for in Section five of this Act shall not authorize the holder thereof to prescribe drugs in the practice of osteopathy, nor (or) to perform major or operative surgery. And any person holding or practicing under this Act, who shall prescribe or use drugs in the practice of osteopathy, or who shall perform major, minor or operative surgery, shall be deemed guilty of a misdemeanor provided that nothing in this Act shall be so construed as to prohibit any legalized osteopath in this State from practicing major or operative surgery after having passed a satisfactory examination in surgery before the State Board of Medical Examiners of the State of Montana."

In 1905 (Laws 1905, page 109) this section was amended by deleting or omitting the word "minor" italicized above. The osteopath contended that the legislature by omitting "minor" in the 1905 amendment clearly intended to permit osteopaths to practice minor surgery, impliedly arguing, of course, that the performance of a tonsillectomy was minor surgery. The Supreme Court, however, refused to adopt such logic. The omission of "minor," said the court, in the 1905 amendment was obviously done to clarify the section and to make it uniform wherever it referred to operative surgery. According to all medical authorities "operative surgery" includes both major and minor surgery and we have no doubt the legislative assembly believed the term "minor" was superfluous.

In 1907 the section of the medical practice act, in effect, defining the practice of medicine was amended (Laws 1907, chapter 101) by adding the following proviso:

Provided, however, that nothing in this section shall be construed to restrain or restrict any legally licensed osteopathic practitioner practicing under the laws of this state.

The osteopath apparently contended that the effect of this proviso was to render the provisions of the medical practice act inapplicable to the activities carried on by a legally licensed osteopath. The Supreme Court, however, did not believe that the proviso adopted in 1907 in any way broadened the power of licensed osteopathic practitioners. In support of its holding it quoted from its prior decision in *State v. Dodd*, decided in 1915, and reported in 149 P. 481, reading in part, as follows:

Counsel for appellant insists that the effect of that section, with the proviso quoted [referring to the proviso under discussion here], is to deny to every person, except osteopaths, the right to practice medicine or surgery in Montana, and that, in excepting osteopaths from the operation of its provisions, those persons thus favored are free to engage in the practice of medicine and surgery without having to submit to the ordeal of an examination and without having the certificate required of every other one who seeks to engage in like practice.

The proviso in section 1591 [referring to the proviso under discussion here] is a harmless piece of legislation. It did not affect the status of osteopathic practitioners in the least. They were confined thereafter, as theretofore, to the practice of osteopathy and forbidden to practice medicine or surgery without the certificate from the state board of medical examiners required of everyone who seeks to engage in such practice.

[The section of the osteopathic practice act defining osteopathy provides] "Every person shall be deemed practicing osteopathy within the meaning of this act who shall, treat, cure, alleviate or relieve any ailment or disease of either mind or body, or bodily injury or any fracture or misplacement or abnormal condition, or method of manipulating any deformity, by any treatment, or manipulation or parts, by the use of the human body or any of its limbs, muscles or parts, by the use of the hands, or mechanical appliances, in an effort or attempt to relieve any pressure, obstruction, misplacement or defect, in any bone, muscle, ligament, nerve, vessel, organ or part of the body." Within the entire scope of his practice, the osteopath is confined to treatment by the use of the hands or mechanical appliances.

The court then quoted from *State v. Wood*, 165 P. 592, as follows:

In *State v. Dodd* [citation omitted], we considered these statutes at length and concluded that the practice of medicine and surgery does not include the practice of osteopathy, and that the practice of osteopathy does not include the practice of medicine or surgery, that the Legislature has grouped all persons practicing the healing art into two distinct classes, (1) physicians and surgeons, and (2) osteopathic practitioners and that the so-called proviso added to section 1591 above [referring to the proviso discussed in this case] "did not affect the status of osteopathic practitioners in the least. They were confined thereafter, as theretofore, to the practice of osteopathy and forbidden to practice medicine or surgery without the certificate from the state board of medical examiners required of everyone who seeks to engage in such practice." We are more than ever confirmed in the correctness of those conclusions. The so-called proviso found in section 1591 [referring to the proviso quoted in this case], and the like provision in section 1603b [referring apparently to the section of the osteopathic practice act stating the scope of the license to practice osteopathy], were doubtless enacted out of abundance of caution and to emphasize the legislative intention that neither school of practice should be held to infringe upon the other.

The attorney general, continued the Supreme Court, the attorney who appeared as *amicus curiae* in the argument of this case before this court and this court itself are in accord on the propositions that operative surgery includes all surgery and that the omission of the word "minor" in the 1905 amendment to the osteopathic practice act does not authorize osteopaths to perform surgery of any kind, either minor or major. We think it is clear that osteopaths have no right to perform surgical operations on human beings unless they are licensed to do so by the state board of medical examiners.

The osteopath next contended that if he was guilty of any offense at all it was that of practicing surgery without a license, whereas he was charged in the information with practicing medicine without a license. The practice of medicine and the practice of surgery, answered the court, are considered as one under our statutes and under long acceptance by people generally, and there is no authority that we have found to justify any different notion about what practicing medicine means. Surgery is described by various authorities as follows:

"That branch of medical science, art, and practice, which is concerned with the correction of deformities and defects, the repair of injuries and diagnosis and cure of disease, the relief of suffering, and the prolongation of life, by manual and instrumental operations." *Webster's New International Dictionary*.

"There cannot be a complete separation between the practice of medicine and surgery, as they are developed by modern science, and understood by the most learned in the two professions, the principles of both are the same throughout, and no one is qualified to practice either who does not properly understand the fundamental principles of both." *2 Bouv. Law Dict., Revue's Third Revision*, p. 3209.

"Therapy of a distinctively operative kind, such as cutting operations." *Century Dictionary and Cyclopedia*.

"The art, practice, or work of treating diseases, injuries, or deformities by manual operation or mechanical appliances, the branch of medicine that is concerned with such treatment." *New Century Dictionary*.

"The branch of healing art that resorts to manual operations or mechanical appliances for the treatment of injuries, deformities, or internal morbid conditions." *Standard Dictionary*.

The judgment of the trial court in favor of the defendant osteopath was accordingly reversed and a new trial was ordered.—*State v. Thierfelder*, 132 P. (2d) 1035 (Mont., 1943).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1933 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Dextrose Deficiency and Cardiovascular Symptoms.—Harrison and Finks emphasize the relationship of certain disturbances of cardiovascular function to a metabolic disorder characterized by the following features: (1) The symptoms practically always occur two or more hours after meals, (2) they can usually be reproduced by the injection of insulin, (3) they can be relieved by the ingestion of dextrose and—in large measure—prevented by dietary regulation, and (4) at the time the symptoms occur the level of the blood sugar is usually either slightly subnormal or within the lower limits of the normal range. The disturbance of carbohydrate metabolism which is responsible for these symptoms has been designated as 'relative hypoglycemia'. It is a common factor in the production of symptoms referable to the circulatory system and has been found in 31 of the latest 204 patients with cardiovascular complaints seen by the authors. Relative hypoglycemia may produce manifestations identical with those observed in patients with cardiac neurosis. The two conditions are difficult to differentiate and they frequently coexist. Relative hypoglycemia may be a 'trigger' factor in precipitating various arrhythmias (including paroxysmal tachycardia) as well as attacks of angina pectoris, hypertensive encephalopathy, carotid sinus syncope and circulatory disturbances associated with the menopause. Relative hypoglycemia is frequently associated with pain in the chest which is nonanginal in character. Occasionally in patients with typical effort angina it induces attacks of angina pectoris at rest. The circulatory manifestations of relative hypoglycemia are the same as those observed after the experimental or therapeutic administration of insulin. They appear to be related to two mechanisms: release of epinephrine and alterations comparable to those which occur in anoxia. The increased venous return so brought about causes an augmented cardiac output and the typical signs of the 'overactive heart'. The attempt to reproduce the symptoms in a given case by insulin administration is a more valuable diagnostic method for certain patients than the dextrose tolerance test. Both methods are less important than the history. When relative hypoglycemia is causing symptoms benefit can usually be obtained by the use of a diet which is poor in carbohydrates

and rich in protein with intermediate feedings. Observation of the response to such a diet is therefore at times a helpful diagnostic measure.

Embolism and Secondary Thrombosis of Bifurcation of Aorta.—Herrmann and his collaborators report 5 cases of saddle embolus at the bifurcation of the aorta, with one recovery, and necropsy studies in 3 cases. The first 2 patients were elderly men with hypertensive arteriolar disease, atherosclerosis, coronary thrombosis and myocardial infarction and mural thrombi. These thrombi gave rise to emboli which lodged at the bifurcation of the atherosclerotic aorta, followed by secondary thrombosis. The third patient was an elderly woman with rheumatic mitral stenosis and insufficiency, atrial fibrillation, vegetative endocarditis, hypertensive arteriolar disease and mural thrombi in all of the heart chambers. An embolus, probably from the left atrium, saddled the bifurcation of the aorta. Arteriosclerosis of the aorta near the bifurcation apparently was responsible for massive, secondary thrombosis. The last 2 patients were younger persons with rheumatic mitral stenosis and insufficiency and atrial fibrillation. They apparently had less aortic disease and survived longer after the emboli lodged at the aortic bifurcation. Both subsequently had cerebral embolism, 1 died and 1 survived. Conservative medical treatment was practiced in all instances. Heparinization and surgical intervention would probably have been successful in some of the cases. The authors stress that patients with coronary occlusion and myocardial infarction and those with rheumatic mitral disease and auricular fibrillation or verrucous endocarditis are candidates for saddle embolism. The bifurcation of the aorta, iliacs or other great arteries are not uncommon sites for the lodgment of relatively large emboli. The secondary aortic thromboses that follow in atherosclerotic aortas are most serious. The occurrence of abdominal cramps should lead one to suspect movement of the emboli down the aorta. Sudden sharp pains in one leg and then in the other, followed by paresthesias, coldness, blanching, lowered skin temperatures and absent or greatly decreased femoral pulses should lead one to suspect lodgment of an embolus at the bifurcation of the aorta. Oscillometric studies are confirmatory of the absence of pulsations. When the embolus is small and the obstruction incomplete, a much less clearcut clinical picture is presented. Papaverine hydrochloride in a dose of 0.032 Gm ($\frac{1}{8}$ grain) intravenously should be started as soon after the onset as possible. Morphine is used to control the pain. Whisky should be administered freely. Passive movements, postural exercises and passive vascular exercise are to be undertaken. Lumbar sympathetic block should be produced to relieve pain and cause maximum peripheral vasodilatation. In elderly persons because of the great likelihood of secondary thrombosis, heparinization should be instituted. Heparinization followed by dicumarol may some day become a routine emergency procedure in the treatment of all cases of massive coronary thrombosis. The patients with rheumatic heart disease seem to have the best prognosis as far as saddle embolism is concerned.

Responses to Carotid Sinus Stimulation in Man.—Galdston and his associates review the history of research on carotid sinus stimulation, giving particular attention to the investigations of Weiss and his co-workers, who distinguished three types of syncope resulting from carotid sinus stimulation. The first, in which syncope is accompanied by definite slowing of the heart rate or asystole and a consequent fall in arterial pressure, is designated the 'vagal type', the second, in which a pronounced fall in arterial pressure occurs without significant slowing of the heart the 'depressor type' and the third, in which there is syncope without either slowing of the heart or fall in arterial pressure, the 'cerebral type'. The authors studied the relationships in point of time, between changes in arterial pressure, pulse rate, venous pressure, respiration and the onset of syncope and convulsions. One hundred persons were examined, 26 of whom presented a sensitive carotid sinus reflex. Of these, 17 regularly had convulsive seizures on stimulation of the carotid sinus. The common circulatory response in the 17 persons was slowing of the heart and asystole (vagal response) with a fall in arterial pressure (depressor response). A pure vagal response was next most common. A pure depressor response was not observed except when the patient was

under the influence of atropine. Paradrine hydrobromide prevented to a large degree the depressor responses. Two patients had convulsions without significant circulatory change (cerebral type). In 3 other patients syncope and convulsions persisted when circulatory changes were inhibited by the administration of atropine or paradrine. Hyperpnea is the regular respiratory response to digital pressure in the region of the carotid sinus. Its occurrence is independent of the circulatory response. It is independent of age or sex. It is not prevented by barbiturate anesthesia, but local infiltration of the region about the carotid sinus and carotid body with procaine hydrochloride abolishes it. Prolonged stimulation is often followed by a phasic type of respiration similar to Cheyne-Stokes breathing. Evidence is presented that hyperpnea after pressure on the neck in the region of the carotid sinus in man may be caused by a disturbance of the blood supply to the carotid body rather than by mechanical stimulation of the carotid sinus.

Effect of Activated Sludge Process on Poliomyelitis Virus—Carlson and his associates investigated the effect of the activated sludge process as used in municipal sewage disposal plants on the removal or inactivation of a mouse adapted strain of poliomyelitis virus. Virus suspension 1:300 was used in sludge concentrations of 1,100, 2,200 and 3,300 parts per million with aeration periods of zero, six and nine hours. The results indicate that activated sludge in amounts as low as 1,100 parts per million with six hours' aeration will remove or inactivate the virus to a sufficient extent to reduce greatly infectivity for mice injected intracerebrally. Heavier concentrations of sludge with longer aeration periods largely eliminate infectivity.

Hypoestrogenic Keratodermitis—Lynch describes 10 cases of hypoestrogenic keratodermitis. Microscopic changes as seen in a study of 5 specimens presented a greater degree of inflammatory reaction than was noted in the case studied by

Haxthausen. Swelling of the collagenous fibers and degeneration of the elastin were also noted. In most cases a favorable effect resulted from administration of diethylstilbestrol for as short a period as one or two weeks. To obtain a cure the treatment had to be continued for several months. It is not possible to point out clinical or microscopic features which allow differentiation of hypoestrogenic keratodermitis from neurodermatitis. It is the author's belief that the palmar and plantar eruption described by Brooke and known as keratoderma chimericum (Haxthausen) is a form of variant of neurodermatitis. The eruption is associated with a disturbed estrogenic activity in so large a proportion of cases that one is forced to regard the association as of major etiologic significance. The favorable clinical response to administration of estrogens is more striking than the occasional moderately favorable influence of these agents on the more common forms of neurodermatitis. These reasons lead Lynch to believe that the disease will be recognized more generally and treated more intelligently if such cases are described under another title rather than under the broad and frequently misunderstood term "neurodermatitis." Because the disease occurs also in women who have evidence of endocrine disorder but are not approaching or passing through the climacteric and because the term keratoderma is not acceptable to authorities on nomenclature, Lynch suggests that "hypoestrogenic keratodermitis of the palms and soles" is a more suitable title than the terms applied by Brooke or by Haxthausen.

Effect of Surgical Operations on Blood Pressure—Adamson and Dubo direct attention to the spontaneous, non-therapeutic, oscillation in blood pressure, because it has been frequently overlooked in judging therapeutic effects. The most recent innovation in the treatment of essential hypertension is sympathectomy. According to some reports, gratifying results have been obtained. All postoperative improvement, whether objective or subjective, is usually attributed to the specific effect of the operation. In view of the known lability of blood pressure and the effect of suggestion on symptoms, these claims demand critical examination. Volinn and Flaxman have produced evidence to show that symptomatic relief and reduction in blood pressure resulting from nonspecific surgical measures, e.g. hysterectomy, prostatectomy and cholecystectomy, in the presence of essential hypertension are similar to and sometimes better than those obtained by extensive sympathectomy, splanchnic nerve section or celiac ganglionectomy. The authors determined blood pressure changes associated with major nonspecific operations and compared them with those claimed for various sympathectomy operations. The blood pressures of 208 patients before and after major operations and 28 additional patients with hypertension who were not operated on were followed during hospitalization. There was a definite reduction in blood pressure in all cases which was similar in the two groups. Alleged specific effects must be measured against known non-specific effects which take place concurrently with all surgical operations. Careful and prolonged observation under various conditions must be made before and after sympathectomy before definite conclusions can be arrived at.

Radiation Treatment of Cancer of Cervix—McCormick reviews the different methods in the treatment of cervical cancer and shows that the combination of x-rays and radium is the best. He describes the technique of this treatment and reviews observations in 135 cases. He arrives at the following conclusions:

clusions 1 Cranioma of the crura should be treated by radiotherapeutic methods without previous surgical intervention and with as little manipulative trauma as possible 2 Roentgen irradiation must be adequate and given without thought of expense 3 This can be achieved with modern 200 kilovolt equipment, but only by the use of long skin target distances and heavy filtration 4 The roentgen irradiation is followed by radium treatment 5 The expense of the patient is comparable to that of any major surgical procedure 6 The results in all but the most hopelessly advanced cases are encouraging, and superior to earlier methods of treatment 7 Patients living and apparently free from cancer at the end of three years may reasonably be expected to remain well for at least a five year period 8 Fifty per cent of patients treated as described are living normal lives five years later

Treatment of Aero-Otitis Media by Redecompression.—Smedal and his associates report that of more than 10,000 individuals who have been subjected to rapid changes in barometric pressure in the low pressure chamber at the U S Naval Air Training Center Pensacola, Fla., approximately 12 per cent have developed "ear block" during descent or recompression in the chamber, and many of the same group presented symptoms and signs of aero otitis media. The precipitating event which precedes the development of aero otitis media is an increase in the ambient pressure without compensatory ventilation of the middle ear by way of the eustachian tube. The resultant relative vacuum is responsible for the vascular hyperemia and fluid exudation within the middle ear, and thus for the symptoms. The treatment by redecompression consisted of a rapid ascent in the low pressure chamber to a pressure altitude which permitted voluntary ventilation of the affected middle ear. In the individuals studied this altitude averaged 5000 feet but varied from 3000 to 8000 feet. It proved necessary to urge each patient to maintain voluntary ventilation of the middle ear by frequent swallowing or a modified Valsalva

maneuver because the course of aero otitis media was marked by periodic recurrences of reduced pressure within the middle ear and the characteristic accompaniments of pain, sense of fullness and diminished hearing acuity. In 27 of a group of 33 men with severe aero otitis media, this form of treatment has effected immediate relief of symptoms and rapid resolution of the process. The failures occurred in patients who for any reason were unable to effect or to maintain aeration of the middle ear during and after redecompression. The simplicity of treatment by redecompression recommends its use in preference to catheterization of the eustachian tube.

Total Cystectomy for Carcinoma of Bladder—Priestley and Strom reviewed the records of all cases in which total cystectomy for neoplasm was performed at the Mayo Clinic from 1910 to Aug 31, 1942 inclusive. In each of these cases a malignant lesion was demonstrated by pathologic examination of a specimen taken for biopsy prior to operation. The total number of patients operated on was 105. There were 51 patients who survived total cystectomy for carcinoma of the bladder. Of these 51 patients 26 have died since operation, 15 of these within the first postoperative year. The remainder died at intervals ranging from one to six and one-fourth years after operation. The cause of death was ascertained for 20 of this group of 26 patients. Metastasis was the cause of death of 16, whereas 4 died of renal failure. Of 13 who died because of metastasis, extension of the carcinoma beyond the bladder was noted at the time of operation. It appears unwise to perform cystectomy if the growth has extended so that its complete removal is questionable. There is a small group of patients who may die some time after operation because of pyelonephritis and its complications, but it is hoped that, as experience with ureterosigmoidostomy grows, the incidence of such renal complications will be reduced. Of the group of 51 patients who survived cystectomy, 24 are still alive and 1 could not be traced. The length of postoperative experience for this group of patients is too brief to permit an accurate estimate of ultimate survival rates. Seventeen have been operated on within the past year. Eight patients are living one to twenty-eight years after operation. Despite the comparatively high operative mortality rate associated with this procedure in years past, total cystectomy has appeared to be the only hope of cure in many cases of carcinoma of the bladder. Indications for the operation remain controversial and will be determined definitely only by more experience. Careful selection of patients and close attention to preoperative and postoperative care as well as to the fundamentals of operative technique have reduced the initial operative mortality rate to a point where total cystectomy can be considered a justifiable procedure.

Pulmonary Embolism Due to Quiet Venous Thrombosis—Homans reports 11 cases of quiet thrombosis in the lower limb causing pulmonary embolism in ambulatory patients. Six similar cases are reported in which an old thrombophlebitis, an injury or an illness had preceded the thrombosis. Quiet thrombosis, or so-called phlebothrombosis, is a noninflammatory, reactionless process. It takes place in the deep veins of the legs, usually below the knees. The peculiar and dangerous quality of a quiet venous thrombosis lies in its decided tendency to form a loose, soft, detachable thrombus. The explanation of the lack of statistics warning the profession of the incidence of quiet thrombosis and consequent embolism lies in this, that the more silent the process the greater is the danger of embolism. A fatal pulmonary accident may come from a leg that even those most familiar with venous thrombosis must consider normal, and by contrast the great swollen leg of thrombophlebitis almost never causes embolism. The original thrombosis may pursue three courses: recovery without extension, development into phlegmasia alba dolens, and formation of a propagating thrombus with pulmonary embolism. Consideration of the cases presented shows that, since pulmonary infarction and embolism often simulate cardiac and pulmonary disease in ambulatory patients otherwise well, they must be considered in the differential diagnosis of many acute and recurrent thoracic disorders. Repeated embolism associated with quiet thrombosis is not rare, the dangerous or fatal quality of any one process is unpredictable, operative treatment to secure interruption of the thrombosed vein proximal to the source of embolism is always indicated. Conservative treatment, even if not followed by further embolism, is unlikely to prevent continuance or recurrence of the thrombosis. The use of heparin does not protect against repeated embolism and a fatal outcome.

Vitamin K₁ Oxide in Hypoprothrombinemia Induced by Dicumarol—Davidson and MacDonald show that dicumarol as an anticoagulant has advantages over heparin, such as activity when given by mouth and relatively low cost, but it has the serious disadvantage of lack of control. Several investigators have demonstrated that vitamin K has an action antagonistic to dicumarol. The authors were able to reverse the hypoprothrombinemia produced by dicumarol in 3 out of 4 patients by administration of large doses of vitamin K₁ oxide. It is probable that an inadequate amount of the vitamin was administered to the fourth patient. In 1 patient the administration of vitamin K₁ oxide prevented the subsequent establishment of a hypoprothrombinemia following the administration of dicumarol. The amount of vitamin K₁ oxide required to produce the desired effect varied considerably from patient to patient. No serious toxic manifestations were observed from the administration of large amounts of the vitamin. The only untoward action observed was transient headache and, in 1 patient, vomiting. It is suggested that the action of vitamin K₁ oxide in reversing the hypoprothrombinemia established by single doses of dicumarol may make the therapeutic use of this anticoagulant safer than it has been heretofore.

Early Diagnosis of Cancer of Colon—Estes reviewed 40
proved cases of cancer of the large intestine to ascertain some
criterion whereby cancer of the colon might be suspected from
its first manifestations. He found that in 85 per cent the first
complaint was abdominal pain or intermittent colic associated
with constipation and relieved by the passage of gas or defeca-
tion not accompanied by obvious change in stools. After it
was recognized that these symptoms are suggestive of cancer
of the large intestine, a particularly exhaustive investigation of
patients presenting these symptoms was undertaken. As a
result, in the next one and a half years the resectability rate
for cancer of the colon increased from 45 to 85 per cent. The
author concludes that all persons, especially those over 40 years
of age, with a change in bowel habit and with unexplained local
abdominal pain, intermittent gas cramps or distention should be
suspected of having a cancer of the colon until proved other-
wise. Persons presenting these symptoms should have an
exhaustive clinical survey including bimanual rectal and pelvic
examination, sigmoidoscopy, x-ray study, test for occult blood
in the stool and peritoneoscopy when indicated. If these cases
are suspected and proper investigation made, cancer of the large
intestine can be discovered in a sufficiently early stage to permit
radical surgical resection and cure.

Jaundice Following Administration of Human Serum
—Oliphant and his associates studied hepatitis following the
use of yellow fever vaccine when an outbreak occurred in the
Virgin Islands in the summer of 1942. A total of 11,358 indi-
viduals on the islands of St Thomas and St John was inocu-

lated with lot 331 yellow fever vaccine containing pooled human
serum. The vaccinations were performed between March 4 and
March 28, 1942. Jaundice was first noted in May. It was
estimated that between 300 and 500 cases occurred. A survey
revealed that among the vaccinated population the incidence of
jaundice was 14.7 per cent. The disease varied from very mild
to extremely severe cases. It seems evident from the prolonged
incubation period and from the clinical symptoms that the
disease under observation was identical with that previously
described and designated as homologous serum jaundice. In
experimental studies the authors produced jaundice by inocula-
tion of two lots of yellow fever vaccine containing pooled human
serum. Jaundice was produced by the inoculation of small
amounts of filtered serum from 2 individuals and a group of 9
individuals who had previously received yellow fever vaccine
containing human serum. The jaundice producing agent is
filtrable and survives drying in vacuum storage for long periods
in serum at 4 C and heating to 56 C for one-half hour in the
dried state. Evidence is presented that the jaundice producing
agent is present in the blood before jaundice appears but not
two and one-half months after disappearance of jaundice. There
was evidence suggesting that the jaundice producing agent may
be neutralized by ultraviolet irradiation. The sexes are appar-
ently equally susceptible. Transmission of this type of jaun-
dice by ordinary contact has not occurred during this study.
Attempts to produce jaundice in experimental animals and to
develop a complement fixation test were unsuccessful. It was
recognized in 1942 during an epidemic of jaundice in the United
States Army that some agent in human serum employed as a
diluent in yellow fever vaccine was probably responsible. The
yellow fever vaccine now in use does not contain serum and
so far has not produced jaundice.

Preoperative Roentgen Therapy of Breast Carcinoma
—Analysis of 12 cases by Dann and Koritschoner reveals that
complete sterilization of carcinoma of the breast and axillary
nodes by fractionated irradiation has not been accomplished.
Irradiation brings about a definite reduction in the size of the
tumor and pronounced regressive changes, which may be due
to the enhancement of the natural defensive reaction of the
host. Operable carcinoma of the breast should be treated by
radical amputation. The additional benefit derived from pre-
operative irradiation of operable carcinoma remains to be
established. Inoperable carcinoma may become operable after
irradiation. Radiation therapy is recommended in inoperable
carcinoma, operable carcinoma for which operation is refused
and operable carcinoma with physical conditions contraindicat-
ing operation. Further studies of the individual factors
governing irradiation may disclose an improved technique for the
treatment of carcinoma of the breast. The authors suggest that
a comprehensive centrally controlled plan of investigation be
inaugurated to establish the precise value of radiation therapy
of breast carcinoma.

 Night Blindness of War P H Wosika—p 331

Primary Pulmonary Coccidioidomycosis—Goldstein and Louie state that primary pulmonary coccidioidomycosis is a relatively uncommon but important infection. It is uncommon because its etiologic agent, *Coccidioides immitis*, must exist under certain climatic conditions which, according to present knowledge, occur in this country only in certain western states, notably California and Arizona. It is important because the disease is protracted despite its excellent prognosis. This importance becomes manifold at the present time because of the presence of many troops in or near areas where it is endemic. With the current flux of troops, bearing in mind the incubation period, one cannot emphasize too pointedly that this entity may present itself to the medical officers in foreign and in domestic stations aside from the regions where it is endemic. The authors report an epidemic of 75 cases of primary pulmonary coccidioidomycosis. The history reveals exposure in a region where coccidioidomycosis is endemic, with symptoms of pain in the chest, chills, fever and cough. Positive physical findings may or may not be present, but they are not in themselves diagnostic. It is suggested that cervical adenopathy with sore throat but without a pharyngitis may be an early characteristic of this disease. A positive cutaneous reaction to coccidioidin and x-ray appearances aid in establishing the diagnosis. A conclusive diagnosis is made by cultures of sputum and by serologic tests. The prognosis is excellent. Treatment is symptomatic, emphasis is placed on rest in bed, adequate intake of fluids, high calory and high vitamin diet, sedatives and anal-

gesics. The sedimentation rate was the primary factor in the determination of the resumption of activity by the patient, an arbitrary standard requiring a sedimentation rate of 15 mm or less in sixty minutes with complete absence of symptoms was established as the point at which a patient was allowed out of bed. Convalescent blood from two donors with high precipitin titers was used for transfusion of 2 patients who were critically ill. Both patients demonstrated immediate clinical improvement after the transfusions. Evaluation of this type of therapy cannot be deduced from these 2 isolated instances.

Night Blindness of War—According to Wosika, night blindness of war was first reported during the Crusades and since that time almost all major military efforts have been accompanied by night blindness, particularly wherever overstraining, heat, sun blinding, hunger and thirst have occurred. The first world war was responsible for much literature on this subject. The term night blindness of war embraces organic and idiopathic night blindness. In the literature poor dark adaptation as measured by instruments also has been included under this term. Malnutrition (lack of vitamin A) causes night blindness, xerosis and xerophthalmia. Therapeutic correction is simple, swift and sure. Poor dark adaptation does not seem related to night blindness, xerosis, xerophthalmia or food adequacy. Therapeutic correction is not successful even with huge supplemental doses of vitamin A. In the present state of knowledge of scotopic vision, night blindness and poor adaptation must be differentiated. It is suggested that further work with the rate and end values of dark adaptation concerning rods, cones and influences of the nervous system be performed in an attempt to establish a firm physiologic basis for dark adaptation tests. While dark adaptation tests do measure the ability to see in low luminosity, the controlling mechanism is not established, the relation to vitamin A is not clear and its usefulness in military medicine as regards night blindness of war must be questioned, although further refinements of technique may enhance the value of the test.

Trichinosis Epidemic—A man complaining of muscle pain, swollen jaws and puffy eyes following a gastrointestinal upset was admitted to a Janesville hospital. A routine blood smear showed eosinophilia and suggested trichinosis. It was discovered that many members of the neighboring community were afflicted with similar complaints. The epidemic involved 28 patients from 13 families. There was a history of eating summer sausage obtained from a local butcher and followed in a week by illness. The sausage was made from contaminated pork. Since summer sausage is not treated by cooking or refrigeration, the encysted larvae were not killed. Symptoms referable to the gastrointestinal tract, the eyes and the muscles predominated. Chills and remittent fever with signs of meningitis were common. Cardiovascular signs, weight loss, and cough were observed. The blood picture showed eosinophilia, the curve paralleling the course of the disease. Relative lymphopenia was common. Blood calcium was low in 2 cases. The acute phase lasted three or four weeks, with residual symptoms of weight loss, weakness and eosinophilia. Purging with castor oil and calomel was of doubtful benefit, it was probably started too late to be effective. Cod liver oil and calcium, with some parathyroid injection, were given in large doses in 1 case. Despite the low blood calcium, only 48 mg in 1 case and in another 44 mg, those without treatment did as well as those with it. No anemia developed though the red blood cells fell a few hundred thousand in the cases studied.

Smallpox Treated with Sulfanilamide—Cottrell and Knights report observations in 11 cases of smallpox which they observed in the course of a civilian epidemic of the disease, which occurred in an area in the Middle East Command. In the area in which the majority of the reviewed cases occurred, there were reported 444 cases, a figure estimated to represent about one third of the total incidence. The estimated mortality was about 20 per cent. Nine of the 11 cases occurred among British troops, the other 2 involved one of the authors and a Nursing Sister. In 4 of the 11 cases no vaccination scars could be detected. Of these 4, 3 were fatal. In all the others there were good "baby" scars. It is considered that the effect of a good "baby" vaccination is sufficiently long lasting demonstrably to modify the effect of an attack of smallpox occurring twenty to thirty years later. The treatment consisted in addition to general and symptomatic measures of administration of sulfanilamide. Treatment was commenced as soon as the vesicular stage was reached, and the average total dose was 22.5 Gm given over six days. The main, if not sole, effect of the sulfanilamide appeared to be the reduction of complications due to pyogenic organisms, no effect was detected on the essential virus. There was definite mitigation of suppuration in the skin lesions, a lessening of ocular complications and a reduced incidence of pulmonary complications. Instead of a true pustular stage there was a vesicular stage in which the vesicular fluid was slightly milky and not yellow even in cases with a fatal outcome. The process was later one of desiccation and desquamation rather than of the classic pustulation and scabbing.

Toxicity of Tannic Acid—Cameron and his associates report an experimental investigation into the toxicity of tannic acid and the chances of its absorption from burned areas. Some information about the fate of tannic acid after it reaches the circulation is given and contrasted with the behavior of gallic acid. Experiments have been carried out on goats, rabbits, guinea pigs and rats, 250 animals being used in all. Tannic acid was obtained from seven different firms but one sample was employed for most of the experiments. This sample contained about 20 per cent gallic acid. The authors present experimental evidence that in animals tannic acid has injurious effects on the liver, capillaries and possibly on the bone marrow. After the introduction of small amounts of tannic acid directly into the blood stream or large amounts into the subcutaneous

tissues, animals show centrilobular necrosis in the liver, increased capillary permeability with leakage of plasma into the subcutaneous tissues, peritonium and occasionally the lungs, and leukocytosis. Production of a reservoir of tannic acid in the tissues, as by subcutaneous injection, leads to continued absorption of small amounts into the blood and a serious intoxication. Treating a burnt surface may also be followed by absorption of tannic acid. With lapse of time the continuous bathing of the liver cells with blood containing tannic acid results in damage and destruction of certain tissues. The injurious effect cannot be attributed to gallic acid, which is rapidly removed from the blood and can be tolerated in large amounts. The authors point out that the chief criticism of tannic acid treatment of burns comes from the experimentalists. Caution must be exercised in applying to man without discrimination conclusions reached by the study of animals. They recognize that the ultimate decision for or against the tannic acid method must come from human experience, and they note that evidence is already accumulating which suggests the need for critical revision of this treatment.

*Relation of Tuberculous Meningitis to Organic Focal Tuberculosis R F Vaccarezza F C Tucci and J B Comez—p 146

Artificial Pneumothorax and Pneumolysis—Vaccarezza and Medici state that artificial pneumothorax should be instituted early in the course of pulmonary tuberculosis. When pneumolysis is necessary it should be done three or four months after the pneumothorax. The Jacobaeus-Maurer type of operation is the most satisfactory. In 300 cases of pulmonary tuberculosis treated by this method and followed for a period of from one to three years, good results were observed in 77.3 per cent. This figure includes cases reported as apparently cured as well as those with a favorable course. There was no surgical mortality. Later in the course of the disease 7.3 per cent of the patients died. The efficiency of pneumothorax combined with pneumolysis is dependent on how early collapse therapy is instituted and on the completeness of the collapse obtained.

Tuberculous Meningitis and Focal Tuberculosis—The study of 90 patients of different ages with tuberculous meningitis showed that it constituted an isolated process in 34.4 per cent and was associated with focal lesions in 65.6 per cent. Focal pulmonary tuberculosis was present in 53.3 per cent. Of these cases 25.5 per cent were primary, 47.7 per cent secondary and 26.6 per cent tertiary tuberculosis. The infant was much more subject to the development of meningitis. Roentgenologic examination revealed fresh lesions of primary infection in 42.2 per cent, calcified lesions of primary infection in 11.1 per cent, juxtahilar infiltration in 6.6 per cent, fresh or calcified hilar shadows in 86.7 per cent and tertiary pulmonary tuberculosis in 26.4 per cent. In no case did the x-rays reveal a "healthy" lung.

Liver Function in Cardiac Insufficiency—Chavez and his co-workers studied the liver function of 35 patients with heart disease, 30 of whom were decompensated. An increase of blood bilirubin and urobilinogen in the urine and a retention of bromosulphalein was observed in all patients with cardiac insufficiency. There was a very close correlation between the degree of liver dysfunction and the severity of heart insufficiency. In the compensated cardiac patients the liver tests were, as a rule, normal. In those with cardiac decompensation the blood bilirubin and urinary urobilinogen returned to normal and the bromosulphalein gave normal results when compensation was reestablished.

- Cancer Mortality in City of Buenos Aires During 1941 A H Roffo—p 615

Extraction of Tar from Tobacco—Roffo shows that the extraction of tobacco with organic solvents such as alcohol, chloroform, acetone, petroleum ether, paraffin and benzene removes from it substances generating carcinogenic hydrocarbons which are to be found particularly among the phytochemicals. The carcinogenic action of these extracted tars has been slight when compared with that of whole tars. Smokers could be provided with tobacco the tar content of which would have only slight carcinogenic action but because the extracted tobacco would have lost much of its taste the author considers it doubtful that the tobacco would be acceptable.

Ultra High Voltage Roentgen Therapy for Mediastinal Tumors—The Roffos report 2 instances of ultra high voltage roentgen therapy. The first patient was a girl aged 18 with a large lymphosarcoma of the mediastinum and a metastasis in the lumbar vertebral column. She was treated with 600 kilovolts, receiving two series of 6,040 and 6,174 roentgens respectively. A year and seven months after completion of the treatment the patient was found cured clinically and roentgenologically. The second patient was a man aged 33 with a large mediastinal tumor and abdominal and lumbar metastases. He too was found well one year after treatment with ultra high voltage roentgen therapy.

- Therapeutic Attempts to Promote Local Blood Perfusion of Tissues in Varicose Crural Ulcers Kite Pezold—p 116
- Successful Roentgen Irradiation in Case of Pulmonary Echinococcus H Brodersen and A Buding—p 118

Prognosis of Arterial Hypertension—Weitz is concerned with a condition which Volhard designates as red hypertension. With the same degree of hypertension the threat to life is greater in younger than in older persons. The highest level of the mortality curve for persons with hypertension is about ten years below that of persons with normal blood pressure. The prognosis is to some extent determined by the treatment, particularly by the degree to which the patient follows the regulations of his mode of living. An enlarged heart indicates that hypertension has existed for some time, but, as a physiologic result, it does not make the prognosis more unfavorable. A systolic murmur over the apex is more frequent when there is insufficiency, but it is of no prognostic significance if other symptoms are absent. A rapid pulse is an unfavorable prognostic sign. Occasional extrasystoles are of no particular importance, but pulsus alternans is an unfavorable sign. The presence of cardiac insufficiency causes stasis in the pulmonary circulation and may signify relative insufficiency. Urinary changes (protein, erythrocytes and casts) indicate an unfavorable prognosis. Changes in the fundus oculi is a serious sign in patients with hypertension. Cerebral defects manifested by impairment of memory, neurasthenia and irritability indicate an unfavorable prognosis. A history of syphilis, the presence of obesity and diabetes render the prognosis less favorable.

Therapy of Varicose Crural Ulcer—Pezold stresses that only those measures constitute a causal therapy of crural ulcer which counteract the pathologic blood perfusion of the lower extremity that exists in this condition. At the dermatologic

clinic of the University of Berlin emphasis is placed on the dietetic treatment of Bommer, which provides large amounts of fruit juices, fruits and vegetables, and on physical therapy. The administration of adenosine triphosphoric acid and of ovarian extracts served as supporting measures. These latter substances promoted the therapeutic effects of the other treatments but had no effect when given alone. The author reviews observations on 25 women with varicose crural ulcers. Some were treated with Bommer's diet, hydrotherapeutic measures and the aforementioned supporting measures, others only with diet and hydrotherapy, and still others only with glandular extracts. The results were most favorable in the first group. The endocrine substances alone were without noticeable influence.

- What Every Physician Should Know About Rectal Cancer Guleke—p 7
- Treatment of Sweet Gland Abscesses H J Lauber—p 11

Sudden Heart Death—Zettel reports the clinical histories and the postmortem findings of 14 patients, a number of them soldiers, who died suddenly. There were 2 cases of rupture of the aorta (one a ruptured aneurysm), 5 cases of valvular lesions or endocarditis and myocarditis, and 7 cases of coronary changes. The patients were exceptionally young, their ages varying between 22 and 47 years. In addition to the organic changes, functional factors played a part as eliciting causes in the sudden heart deaths. The question of impairment by military service is discussed. Careful attention should be given to the presence of circulatory disorders during the preinduction examination. Functional tests of the heart should be included in the general examination. In deciding the suitability for flying service, electrocardiographic studies should be made.

Transmission of Poliomyelitis Virus from Human Subjects to Ferrets—Patočka reasoned that it would be desirable to find an animal other than the monkey for the transmission of the human virus, for this would make possible the production of vaccines for preventive immunization. The monkey virus is too close to the human and consequently is too dangerous for use in human subjects. The author took advantage of the poliomyelitis epidemic of October 1939 and inoculated a number of ferrets intracerebrally with the spinal cord tissue of fatal cases of poliomyelitis. In three different instances in which material was obtained from rapidly fatal cases ferrets developed fever, parietic symptoms and paralytic symptoms. Two ferrets died with symptoms of poliomyelitis. From one of these the virus could be transmitted to a second ferret, which died with the same symptoms after a longer period of incubation. Rabbits, guinea pigs and mice which were inoculated simultaneously with the ferrets failed to develop signs of the disease. Further studies excluded the possibility that the ferrets suffered from a nonspecific irritation of the central nervous system caused by heterogeneous spinal substance or from a spontaneous ferret encephalitis. The spinal cord of the ferrets showed considerable degeneration of the motor cells of the gray spinal substance, but the inflammatory changes were not quite adequate for poliomyelitis. The author explains this by the fact that the virus had taken root in a less susceptible species of animal. He admits that his experience was exceptional and that it will probably not be possible to transmit regularly the virus of human poliomyelitis to ferrets. The exceptional virulence of the virus was probably responsible for the successful transmission.

Book Notices

The Etiology of Delinquent and Criminal Behavior A Planning Report for Research By Walter C. Reckless. Bulletin 0. Paper 11c. \$1.50. Pp. 169. New York: Social Science Research Council, 1933.

In this interesting monograph the author attempts an evaluation of the important contributions and theories on the causes of criminal behavior and suggests a plan for further research. "The present monograph then may be looked on as an attempt to promote unified effort by the different disciplines—psychiatry, psychology and sociology—engaged in the study of the causes of delinquency and criminal behavior." In the complex field of criminology, heredity, subnormal intelligence, mental abnormality, endocrines, physical types and mental types, i.e. 'typical criminal,' have been offered as the deciding factors largely by psychiatrists and other physicians. Sociologists, on the other hand, have emphasized economic conditions, environmental conditions, family situations and exposure to crime, to name a few of the factors held responsible for conflict with the law. The author describes each of these hypotheses and attempts to point out the fallacy of attempts to give them as the sole cause of crime or in some instances to have anything to do with criminal behavior. Throughout the manuscript, emphasis is placed on the author's view that none of the views which have been advanced to date can be accepted as the solution to the problem, but it is obvious that his prejudices favor sociological explanations. He proposes more controlled mass studies as the line of research most likely to give results. In this attempt it is assumed that exhaustive psychiatric studies to all individuals in the group could be added to the environmental data to be collected. This monograph is a valuable contribution to the field of criminology in its effort to bring together research work carried on to date with provocative opinions as to the value of each theory.

A Critical Analysis of Collapse in Underground Workers on the Kolar Gold Field. By Anthony Caplan M.D. M.R.C.P. Reprinted from Bulletin No. 54 of the K. G. I. Mining and Metallurgical Society. Paper. Pp. 95 with 12 illustrations. Marikuppam P. O. Kolar Gold Field India. T. Williams 1942.

This is a discussion of the results of an investigation of the mechanism of heat collapse and its contributory causes in the Ooregum Mysore, Champion Reef and Nundydroog mines of the Kolar Gold Field from Nov. 18, 1939 to Nov. 17, 1941. The factors observed that may have influenced the incidence of heat collapse were individual, seasonal and underground. Individual factors were determined by a careful history and physical examination of all cases (293) of alleged collapse in underground workers admitted during the two years to the Kolar Gold Field Hospital, irrespective of the mildness of the condition or its cause. Seasonal factors were determined by information on surface conditions obtained from the Kolar Gold Field Observatory. Information on underground factors, such as wet and dry bulb temperatures, humidity and velocity of air at the working places, was obtained from the mine superintendents.

The patients were classified into three groups according to whether their collapse was due entirely to underground conditions partly to underground conditions and partly to individual factors or collapse was absent or unrelated to underground conditions. Two types of cases were determined clinically—mild and moderate and severe.

The most interesting data deal with the 200 cases in the second group in which the individual factors were unacclimatization loss of acclimatization and disturbances of health. An unexpected lower incidence of collapse among unacclimatized new employees shows that acclimatization to hotter underground atmospheres existing on deeper levels cannot be developed by many months of continuous work on the cooler levels. Loss of acclimatization appeared to be much more important in predisposing to heat collapse than unacclimatization. The health disturbances that predisposed to collapse were febrile illnesses, after effects of celebrating festivals food intake and nutrition, and water and chloride deficiency.

The pathologic physiology of collapse is discussed in terms of changes in the cardiovascular system and water and chloride metabolism. Many of the symptoms of collapse could be attributed to chloride deficiency. An interesting feature was the

correlation of the incidence of collapse with the rise and fall of surface dry and wet bulb temperatures and humidity which was clearly established and provided positive evidence of the deleterious effect of high surface humidity.

The great importance of ventilation is emphasized by the occurrence of collapse most frequently below 5,000 feet in dead ends supplied with upward air of low velocity. It is stated that, provided the dry bulb temperature is 110-120 F., a wet bulb of 90 F. or under denotes good ventilation and comfortable working conditions, 91-93 borderline working conditions, 94-95 poor ventilation, and 96 or over conditions highly conducive to collapse. The occurrence of collapse depended more on the nature of the working conditions than on the character of the work.

The problem of the mining engineer is to prevent the wet bulb temperature at the face rising above 93 F. The value of air refrigeration is demonstrated by the dramatic fall in the incidence of collapse in the Champion Reef mine after installation of the air conditioning plant and the general low incidence, throughout the two year period, of collapse in the air conditioned Ooregum mine. It is stated that surface air conditioning plants will reduce the incidence of heat collapse for some years, but with further development of the mines it again will become a major problem, taxing the ingenuity and resourcefulness of the mining engineer.

The Human Eye in Anatomical Transparencies Explanatory Text By Peter C. Kronfeld M.D. Director of Education The Illinois Eye and Ear Infirmary Chicago. Anatomical Transparencies By Gladys McHugh Medical Illustrator University of Chicago The University of Chicago Historical Appendix By Stephen J. Polyak M.D. Professor of Anatomy The University of Chicago. Fabricated Price \$6.50. Pp. 99 with illustrations. Rochester New York: Baugh & Lomb Press, 1943.

A new method of graphic representation, namely three dimensional illustration on cellulose acetate, is utilized in this volume to present the finest representation of the anatomy of the eye thus far available. A series of paintings showing serial dissections of the eye and orbit from the front and from the side at twice natural size has been prepared by Miss Gladys McHugh and republished on cellulose acetate so that one can actually see the anatomy of the eye layer by layer. The colors are natural and have been faithfully reproduced except in the case of veins and nerves, which have been made blue and yellow to distinguish them from the arteries. The text prepared by Dr. Peter C. Kronfeld gives a detailed study of anatomy of the eye and in addition a most complete description of the anatomy as shown in Miss McHugh's illustrations. Finally the book includes a history of anatomic illustration of the eye by Dr. S. L. Polyak, a real contribution to medical history on a par with previous histories of medical illustrations such as that of Mortimer Frank. Every ophthalmologist and every teacher, particularly of the anatomy of this subject, will find this book invaluable. Indeed it is reported that the demand is already well beyond the available supply.

Pharmacology Materia Medica and Therapeutics By Charles Solomon M.D. F.A.C.P. Associate Attending Physician and Chief of the Medical Clinic Jewish Hospital of Brooklyn. Collaborator Hazel Houston M.A. R.N. Instructor in Materia Medica School of Nursing Bellevue Hospital New York City. Fifth edition. Cloth. Price \$3.25. Pp. 823 with 91 illustrations. Philadelphia London & Montreal: J. B. Lippincott Company 1943.

The author of Proverbs said "With all thy getting, get understanding." The authors of this book assume that the student nurse has ability and time to become omniscient. They present a pot-pourri complex enough to confuse a witch of Endor. That their presentation aids or gives time for understanding is questionable. They encourage the neophyte with this advice: "The student's mastery of materia medica will be greatly enhanced by her ability to connect the facts and theories in the subject with the facts and theories of related subjects."

The student will therefore do well to make an effort to relate what she learns in materia medica with what she has already learned in anatomy, physiology, chemistry and bacteriology. Wonderful words, but even the authors do not live up to them. In a discussion of some of the major present day problems, proprietary medicines receive the conventional condemnation. The authors give a list of the differences in price of proprietary and ethical drugs which is either not understood or is used as propaganda. For example, the difference in the price of aspirin and acetylsalicylic acid is a wholesale price and

does not affect the retail purchaser. They do not give the devil his due. They give a list of some common names for drugs or preparations such as Bashin's Mixture, Brown Mixture, Bulow's Solution, Channing's Solution, Clemen's Solution, Dalby's Carminative, Warburg's Tincture and Zambicetti Solution. These names are worse than worthless and their use should receive the same condemnation as proprietary preparations. They retard scholarship by using time and space that should be given to more important subjects. Because the book contains so much unimportant matters the discussion and explanation of worth-while subjects is limited to brief and unsatisfactory statements. This applies particularly to the connection of physiology with pharmacologic action, the importance of which they emphasize in the first part of the book but neglect later. The book is clearly written and contains many fine illustrations and a lot of facts not found in many of the better known books on pharmacology. It has an elaborate general lex and an index of symptoms of most diseases.

The Medical Use of Sulphonamides. Medical Research Council War Memorandum No 10. Paper. Price 25 cents. 9d. Pp 46. New York: British Information Services. London: His Majesty's Stationery Office, 1943.

This booklet is a concise presentation of the present status of the sulphonamide compounds with a maximum of facts and a minimum of wasted words. The pages are crammed with information presented in a manner especially suitable for those who wish an accurate view of these agents without encountering confusing and frequently questionable details. The contents encompass an introduction and discussions on chemistry, pharmacology, general considerations governing the use of sulphonamides, questions of supply (in Great Britain) general scheme of dosage, regulation of dosage by the sulphonamide content of the patient's blood, treatment of specific infections, toxic reactions to sulphonamides, estimation of the concentration of sulphonamides in body fluids, bacteriologic studies and sterilization of sulfanilamide powder.

This memorandum has been prepared for the Therapeutic Requirements Committee (appointed by the Medical Research Council) by several well known authorities. Their attitude and conscientious approach to the subject is made evident by their preference for recognized nomenclature, "To avoid confusion and difficulties in supply, sulphonamide drugs should not be ordered or prescribed by proprietary or brand names," and prescribing in terms of the metric system, "Doses should be ordered and recorded in terms of grammes and not in terms of tablets, since not all the sulphonamide tablets issued commercially are of standard 0.5 gm content." The plea for use of recognized nomenclature is refreshing in a country where trade names are rampant, and should be well received and encouraged. The contributors list names under which sulfanilamide is sold or described, the number is greater than fifty for this single drug, an excellent reason for the use of scientific nomenclature.

An Atlas of Anatomy in Two Volumes. By J. C. Boileau Grant M.C. M.B. Ch.B. Professor of Anatomy in the University of Toronto, Toronto. Volume I: Upper Limb, Abdomen, Perineum, Pelvis and Lower Limb. Cloth. Price, \$5. Pp 214 with 227 illustrations. Baltimore: William Wood & Company, 1943.

Up to the year 1900 gross anatomy was the major study of preclinical medicine. There was ample time for it. Students dissected the body more than once. Atlases were of great help, and those then made corresponded with the practice of repeated dissection. They were "systematic," showing the bony, muscular, vascular and nervous systems separately. Now the time available for dissection is reduced. Only one dissection is possible. Grant's regional atlas is adapted to this change. Its illustrations show all the "systems" in each region. So the drawings are fewer. Spalteholz has over a thousand, Toldt over fifteen hundred. Grant covers all but the head, neck and thorax with two hundred and twenty-seven. The drawings are accurate and instructive, being carefully made from special preparations. They show more "relations" than did the older atlases, and the atlas is less expensive. The legends under some drawings are in one or two instances puzzling, e.g., on page 83 is "A stage in the exposure of the (common) bile duct, embryological approach." On page 87 are drawings of variations in the bile duct with the legend "Precocious bile passages." The atlas is good and should prove popular with students.

The Common Form of Niacin Amide Deficiency Disease: Aniacinamidosis. By William Kaufman Ph.D. M.D. Cloth. Price \$3. Pp 62. Bridgeport, Conn.: The Author, 1943.

"Aniacinamidosis" is proposed as the name of a disease which the author characterizes by the syndrome resulting from a deficiency of niacinamide as determined by an original "office study" of "more than 150 patients." No laboratory studies were made and no illustrations are included. The symptoms of the disease, as well as its pattern, are stated in detail. A symptom was not considered as characteristic of the disease unless it appeared in at least 30 of the patients studied, disappeared following niacinamide therapy, and reappeared on cessation of therapy. The book is valuable in that it lists the symptoms which may result from a niacinamide deficiency. However, neither the single symptoms listed nor the entire syndrome are sufficiently unique or characteristic for the disease to warrant a positive diagnosis on their presence in a patient. The book leaves the impression that niacinamide deficiencies are vastly more prevalent than generally believed and that the daily requirements of man are considerably higher than those indicated by legal regulations. The author rightly recognizes that a serious weakness in his contribution lies in the absence of objective laboratory studies on his patients. A limited but valuable bibliography is included.

The Australian Army Medical Services in the War of 1914-1918. Volume III: Special Problems and Services. By Colonel A. G. Butler D.S.O., V.D., B.A. Cloth. Pp 1103 with 85 illustrations. Canberra: Australian War Memorial, 1943.

With this volume Colonel Butler completes the task assigned him in writing the history of medical services of the Australian army in the war of 1914-1918. Section I discusses the technical problems of chemical warfare, moral and mental disorders, venereal disease, the influenza pandemic of 1918-1919 and the surgery of repair and rehabilitation. Section II is devoted to the medical services of the naval and the newly created air services. Section III describes dental service, nursing and physical therapy. Section IV continues the story of the invalid soldier, his return home, the medical problems of sea transportation, the reexamination and the technical problem of pensioning. Section V furnishes statistics on the total casualties sustained by all the belligerents. A special feature of this section is a detailed clinical analysis of the figures of mortality and morbidity comprising the life history of the Australian imperial force. The three volumes constitute a valuable contribution to the literature on military medicine.

Problèmes de médecine de guerre. Par Daniel Cordier. Collection "France Forever" sous la direction du Professeur Henri Laugier. Paper. Price, \$1.50. Pp 182 with illustrations. Montréal: Les Éditions de L'Arbre, 1943.

The text is a composite of four articles. They are concerned with the struggle against heat, methods of resuscitation, anesthesia and traumatic shock. The author, who has an international reputation as an experimental physiologist, has presented these subjects critically, clearly and concisely. Although particular emphasis has been placed on the relationships of fundamental physiologic principles to problems peculiar to war, this book would be a valuable addition to the library of the student, the physician and the physiologist. It merits translation.

Air Borne Infection: Some Observations on Its Decline. By Dwight O'Hara M.D., Professor of Preventive Medicine, Tufts College Medical School, Boston. Cloth. Price \$1.50. Pp 111 with 15 illustrations. New York: Commonwealth Fund, 1943.

This little book presents a readable discussion of certain air borne infections with explanations for the decline in incidence of diseases of this group. The book is not closely integrated, it places special emphasis on the experiences of Massachusetts. Neither of these remarks should be interpreted as fault finding, however, since the author makes no claim to exhaustive discussion. Apparently his main purpose in writing this book is to urge that preventive medicine be incorporated to a greater extent in medical practice and that it should not be operated as a detached specialty.

Queries and Minor Notes

THE ANSWERS HEREF PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

MANAGEMENT OF VIRUS PNEUMONIA

To the Editor—Please advise me if you know of any treatment that will shorten the period of morbidity for virus pneumonia infections of the respiratory tract. During last winter we had many cases most of which acted like the persistent head colds alone or in combination with tracheitis and would persist from three to seven or eight weeks causing much discomfort. The sulfonamide drugs have no effect on this infection and I have been treating it as we treated colds before the sulfonamide drugs came on the market. — John D. Blackburn M.D., Thomaston Ga.

ANSWER—The inquirer is to be complimented on resisting the apparently irresistible urge to give some sulfonamide compound for the common cold and for the virus pneumonia. All who have studied the virus pneumonias carefully agree that chemotherapy is without special benefit. If a view (William Dameshek, THE JOURNAL Sept 11, 1943, p 77) recently expressed is correct, namely that sulfonamide compounds given to certain patients with virus pneumonia may bring about a hemolytic crisis, then chemotherapy for this disease is actually contraindicated.

There is no procedure known which will shorten the period of morbidity of the virus pneumonias. The statement that most cases lasted as long as three to eight weeks is somewhat at variance with general experience and leads one to suspect that some secondary infection like the common cold also affected this group of patients.

Several observers, chiefly roentgenologists, state that roentgen therapy aids in shortening the disease, but in the absence of control cases this must be accepted with reserve. Another group reports beneficial effects from the use of "convalescent" serum, with equally convincing evidence. In view of the apparent multiplicity of causes and of the lack of evidence of beneficial effect of convalescent serum in most other infections this approach would not seem to be promising. The use of penicillin has been reported in one case without beneficial effect.

In a benign, self-limiting disease, as represented by the majority of the virus pneumonias during the past year therapeutic restraint should be exercised.

ERADICATION OF FLEAS FROM RESIDENCES

To the Editor—I should like to have some advice on how to eradicate fleas. I have a cocker spaniel and whenever he is kept out of the house for any length of time such as a vacation the house becomes infested with fleas. These pests are tiny black or brown and hard. They hop up from the floor where they seem to like rugs as their hangout. The bite itches and twenty-four hours later an intense itching develops that can be relieved only by scratching off the top of the bite with subsequent scarring. I have used pyrethrum rotenone sulfur and various other sprays all to no avail. The companies that do exterminating work say they know of no method that will absolutely eradicate fleas from the house. As long as the dog is in the house there is some decrease in the number of fleas but not enough to help one's peace. Frequent bathing of the dog helps slightly but the main trouble is getting rid of the fleas in the house. Can you advise me or refer me to some book?

L. M. Harris M.D., Columbus Ohio

ANSWER—Flea infested premises are largely restricted to those where one or several dogs or cats are kept and where there are suitable places for the propagation of these pests—usually there is a badly lighted basement under the house.

Breeding places for fleas should be eradicated. Basement storage places which are difficult to keep clean may be the first point of attack. After any needed cleanup has been finished dogs and cats should be removed from the premises for two weeks or more during which period suitable fly sprays that contain pyrethrum may be employed in the house, including the basement or adjacent quarters where fleas may propagate. Ordinary tallow candles may be placed on the floor at night and these surrounded with sheets of fly paper to aid further in the cleanup.

W. B. Herms (Medical and Veterinary Entomology, New York Macmillan Company) quotes Skinner, who recommends "sprinkling the floor liberally with about 5 pounds of flake naphthalene and closing the room for twenty-four hours." The toxic fumes are said to destroy the fleas in badly infested quarters without material injury.

CONTACT DERMATITIS FROM RAGWEED FAMILY

To the Editor—I am afflicted with dermatitis venenata caused by *Iva xanthifolia*. The following treatments have been failures. Vaccine made from weeds sent to three laboratories at different times. The last time I took twenty-five hypodermic injections, saturated salicylic acid in alcohol fluid extract of *Phytolacca* (poke root) 10 and 50 per cent balsam of Peru in castor oil, 50 per cent ichthammol in glycerin wearing a paper sack over my head when I am out and exposed to the weeds only the exposed parts of the face, neck and hands are affected. I shall be grateful to you for any treatment you may recommend.

M. D. Wyoming

ANSWER—Contact dermatitis or dermatitis venenata from *Iva xanthifolia* or burweed marsh elder, as the weed is usually designated is not uncommon. Two other members, of this genus of the ragweed family *Iva angustifolia* (narrow leaved marsh elder) and *Iva axillaris* (small poverty weed) are also major skin sensitizing weeds. If a patient is allergic to one of these weeds he is usually also sensitive to the other two. The latter plant is a common weed in many sections of Wyoming.

Local treatment in weed eczema is merely palliative as is the case in contact dermatitis of other origin. In contact with the offending weed cannot be avoided, dermatitis will result and the only relief, until frost or a freeze kills the vegetation and gives temporary respite, will be from local applications. Wet dressings of boric acid, 1-20 Burrow's solution or phenolated calamine lotion are as satisfactory topical applications as any.

Varying degrees of relief can be obtained by the desensitizing treatment of the weed sensitive patient with the specific weed oil or oils. These specific oleoresins are usually best administered by the oral rather than the parenteral route.

Before specific therapy is instituted, a weed sensitive patient should be skin tested with all the common weeds in his environment. Weed sensitivity is usually polyvalent, the individual being sensitive to two or more allergenic weeds. Sensitivity to half a dozen or more common environmental weeds is not unusual. Most dermatologists are equipped with acetone extracts of the common weeds for patch testing. Some sixty uncovered tests can be applied in about ten minutes. After a latent period of approximately forty-eight hours skin reactions at the tested sites will reveal the number of weeds to which a patient is sensitive. All weeds giving positive skin tests should be included in the treatment set.

Experience has shown that it requires the ingestion or injection of approximately 2 cc of a specific weed oleoresin to reduce the sensitivity of a patient from the clinical to the sub-clinical stage. This amount is realized by the fractional ingestion of 1 ounce each of the 1-100, 1-50 and finally the 1-25 dilution of the oleoresin in corn oil. Oral treatment for weed sensitivity is outlined by Shelmire (Contact Dermatitis from Vegetation Patch Testing and Treatment with Plant Oleoresins, *South M J* 33:337 [April] 1940). Oral treatment sets containing the specific weed oils to which an individual is sensitive can be obtained commercially on prescription from the Graham Botanical Laboratory, Route 7, Willow Lane Dallas, Texas.

Hypodermic injections of the allergenic weed oils cause local reactions unless well diluted 1-100 or more in some inert vehicle as corn or peanut oil. To obtain a total of 2 cc of the specific oleoresin it would require some two hundred or more such injections. The ordinary weed sensitive patient has not the fortitude to submit to such prolonged therapy. This is especially true when it is realized that the same amount of allergenic oils can be ingested in a period of approximately three to four months. The amount of absorption of the specific oil is the same, regardless of the mode of introduction into the body.

MORPHINE AND PULMONARY EDEMA

To the Editor—When morphine is generally acknowledged to be of considerable benefit in the treatment of pulmonary edema what is the evidence in support of the contention that this drug is contraindicated in those instances in which the edema results from the action of chemical lung irritants such as phosgene?

Lieutenant M. C. A. U. S.

ANSWER—Morphine may be of benefit in the treatment of some instances of incipient pulmonary edema. However, there is no adequate evidence that morphine is of benefit in a frank pulmonary edema from any cause, especially if cyanosis (hypoxia) is present. The consensus is against the use of morphine in the treatment of pulmonary edema due to chemical irritants. Most authors state definitely that morphine is contraindicated in pulmonary edema due to phosgene.

In commenting on this subject Sollmann (A Manual of Pharmacology ed 6 Philadelphia, W. B. Saunders Company

contractions throughout the intermenstrual period. Table 1 summarizes their findings. In a recent review of primary dysmenorrhea, Fremont-Smith⁶ recognizes the importance of the experimental work of Sturgis,¹¹ Moir¹⁰ and Wilson and Kurzrok¹² and believes that the strong "luteal phase" contractions during the first two days of the menses are involved in the production of pain. Bickers¹³ holds a similar point of view.

MATERIAL

During the past several months we have observed 41 female university students with dysmenorrhea of such severity as to incapacitate them. The age distribution, marital status, gravidity and pelvic findings are given in table 2. Sixteen of these patients had previously received glandular therapy and 2 had had dilation

Note the lack of a consistent anatomic defect. Infertility was a complaint by four married patients, and examinations of their husbands disclosed sterility.

and curettage with little or no relief, 9 had had elective appendectomies. In 18 out of 20 patients the administration of diethylstilbestrol (1 mg daily for twenty days following the cessation of menstrual bleeding) resulted in the complete relief of pain at the next period. The two failures missed the expected period and one month later experienced typical painful menstruation—a phenomenon previously observed by Sturgis.¹¹ In 31 of these women, 55 endometrial biopsies were obtained two to four days before the onset of menses. Table 5 shows the microscopic results of these biopsies before and after treatment. In 2 patients severe uterine bleeding followed the administration of diethylstilbestrol and

in 1 case hospitalization for supportive transfusion was necessary. The dysmenorrhea was treated by one of the prescriptions given in table 3.

COMMENT

It is now generally agreed that there is no consistent anatomic lesion in patients suffering from primary dysmenorrhea and that earlier investigators have erred

TABLE 3—Prescriptions for Dysmenorrhea

Prescription 1		Prescription 2	
Acetylsalicylic acid	5 grains	Camphor monobromate	1/2 grain
Codeine	1/2 grain	Atropine sulfate	1/100 grain
Ergotone	1 grain	Papaverine hydrochloride	1/4 grain
Atropine sulfate	1/100 grain	Acetophenetidin	3 grains
Made into one capsule		Acetylsalicylic acid	5 grain
		Made into one capsule	

It is believed that ergotone aids the relief from cramps by increasing intrauterine tone (Kurczok, Moir and Bickers) and thus prevents the uterus from filling up, a condition which leads to uterine spasm and pain. The symptomatic relief obtained through these analgesics (prescriptions 1 and 2) is shown in table 4.

in attributing the cause directly or indirectly to some obvious or obscure anatomic finding, e. g. a retroverted anteverted or infantile uterus, cystic ovaries, presacral neuritis, defective uterine musculature or disturbed innervation. The presence of anatomic defects is apparently incidental and primary dysmenorrhea must be explained on some other basis.

The pain experienced in primary dysmenorrhea is evidently due to uterine contractions. This point of view is confirmed by the experimental work of Moir¹⁰, Kurczok⁴ and Bickers,¹³ who noted that maximum discomfort is experienced during the first two days of the menstrual period at the time of the strongest luteal contractions. Clinically, one can reproduce the typical cramp-like pains of primary dysmenorrhea by inserting a sound within the uterus. Women have also noticed the similarity of these pains to labor pains and after-pains.

Kurczok⁴ first observed that ovulation is a necessary precursor to painful menses. The presence of secretory endometrium (suction biopsy) in our patients and the similar report of Sturgis and his co-workers¹¹

TABLE 4—Primary Dysmenorrhea: Results of Therapy in Twenty-Seven Patients Treated with Analgesics

Syncope	1	3.7	1	100.0	0	0.0	0	0.0

Prescription 1 gave the most consistent relief from symptoms.

support this position. It is also true that the suppression of ovulation by diethylstilbestrol (or other estrogens) prevents the development of secretory endometrium and results in painless menstruation in patients with primary dysmenorrhea.

It is an old clinical observation that primary dysmenorrhea is often completely or partially relieved by childbearing. It is believed that this is due to free-

egress of the menstrual discharge into the vagina through the parous cervix. The accumulation of menstrual fluid within the uterine cavity stimulates 'luteal' contractions until the threshold is reached and pain results.¹⁴ Instrumental dilation of the cervix cannot produce any permanent enlargement of the cervical canal. Obviously there is considerable difference in the permanent effect of a 10 centimeter fetal head and a 10 millimeter Hegar dilator. The Pozzi or Dudley operation (operative enlargement of the cervical canal) or the wearing of a stem pessary are advisedly condemned but it is admitted that they do relieve dysmenorrhea, presumably by inducing permanent enlargement of the cervical canal. It has been suggested that operative or parturient dilation of the canal destroys the nerve endings or ganglion cells within the cervix. The existence of ganglion cells within the cervical substance is open to question, although they are readily found within

TREATMENT

Physicians err in treating primary dysmenorrhea on the principle that it is caused by organic disease or endocrine deficiency. Frequently such patients change from one physician to another and obtain a separate diagnosis from each. The emphasis on organic or functional defects creates a poor mental attitude. In addition, they have frequently approached the menarche already conditioned for a serious ordeal by overzealous relatives and friends. The first objective in treatment should be to assure the patient that she is absolutely normal and to explain in simple terms the basic physiology of menstrual distress.

The second therapeutic objective is the relief of pain. Usually this can be done with simple analgesics, particularly after the patient realizes the nature of her complaint. Prescriptions 1 and 2 recommended in table 4 are for the more severe cases. As a rule it is necessary

† Severe uterine bleeding necessitated hospitalization for transfusions
which was followed by painful menses

the parametrial tissues a location too remote to be affected by cervical dilation.

After the age of 30 years there may be incomplete shedding of the menstrual mucosa, and ovulatory cycles occur irregularly so that painful menses become less severe and less frequent. Except in isolated instances, as women approach the menopause menses are anovulatory and painless. However, some pain may be experienced by women with anovulatory cycles, provided bleeding is sufficient to distend the uterine cavity and stimulate contractions of large enough amplitude.

In primary dysmenorrhea, associated symptoms of backache, nausea, vomiting and headache can hardly be explained on an organic basis. Nausea, vomiting and spells of syncope are probably the nervous reaction of the patient to the pain. The backache may be produced by pelvic congestion or relaxation of pelvic joints. Premenstrual tension as evidenced by abdominal pain, irritability, headache, backache and nervousness, is also on a psychogenic basis and usually does not appear until some years after the patient has been suffering from dysmenorrhea.

only to relieve the pain for the first and second days of the menstrual period. If the patient can be carried along until she has borne a child or until the age of 30 years, medical treatment becomes less essential.

In our opinion operations such as hysterectomy, uterine suspension and presacral sympathectomy are unnecessary in the treatment of primary dysmenorrhea if the patient is properly handled. It is important to remember that encouraging results can be obtained in such patients with almost any kind of glandular product (even with placebos) owing to their psychotherapeutic effect.

CONCLUSIONS

1 Women with primary dysmenorrhea have no consistent anatomic lesions or endocrine deficiencies.

2 Ovulation and a nulliparous cervix are two essential factors in producing primary dysmenorrhea, and they result in uterine distention which stimulates contractions of large enough amplitude to produce cramping pain.

3 The suppression of ovulation by estrogens to produce painless menses is of experimental interest but of questionable value and possibly dangerous.

SIGNIFICANCE OF PHLEBOGRAPHY
IN PHLEBOEMBOLISM

MAJOR MICHAEL E. DeBAKEY

CAPTAIN GEORGE F. SCHROEDER

MEDICAL CORPS, ARMY OF THE UNITED STATES
AND

ALTON OCHSNER, M.D.

NEW ORLEANS

Although visualization of the venous system is frequently referred to as venography, we believe that, since this is a hybrid word being derived from both Latin and Greek, phlebography should be used because it has a true Greek origin *φλέψ*, *phleps*, vein, and *γράφειν*, *graphein*, to write.

Few complications in medicine and surgery are as unpredictable, treacherous and dramatically tragic as the thromboembolic phenomena. Fatal pulmonary embolism in a patient apparently convalescing uneventfully and preparing to leave the hospital is a fearsome and pathetic catastrophe. Whereas the mortality rate in surgical patients has steadily decreased since the introduction of asepsis and continued improvement in surgical technique and anesthesia as well as the more recent development of the sulfonamides, little has actually been accomplished in the control of pulmonary embolism until relatively recently. Indeed there is some statistical evidence to support the belief that the thromboembolic incidence is increasing.¹ That the condition occurs with sufficient frequency to deserve the assiduous and intensive efforts of investigators has been clearly demonstrated by repeated observations. Thus Snell² at the Mayo Clinic and Dietrich³ in Germany found that pulmonary embolism was considered the cause of death in approximately 8 per cent of all autopsies. In a statistical consideration of this subject Gibbon⁴ was able to express the incidence of fatal pulmonary embolism as follows: Of every thousand patients admitted to the surgical wards, 1 will die of pulmonary embolism, of every thousand operated on, 2 will die from pulmonary embolism, and of every hundred postoperative deaths, eight will be due to pulmonary embolism. Other investigators⁵ have found that of every 17 to 20 patients with clinical manifestations of thrombophlebitis 1 will die of pulmonary embolism and 1 in every 6 to 12 who had previous nonfatal embolism will die of a subsequent embolus. These figures demonstrate forcefully that the incidence and consequence of thromboembolic phenomena are of sufficient extent to deserve serious consideration.

Until recently, combative measures in pulmonary embolism have been singularly ineffective. The Trendelenburg operation, which consists of pulmonary embolectomy, has saved relatively few patients with massive pulmonary embolism and cannot be expected to improve the mortality appreciably. Accordingly it became necessary to attack the problem from another approach. This consists essentially in prophylaxis.

Since an embolus has its origin in a thrombus, prophylaxis should begin with measures designed to prevent intravascular thrombosis. No attempt, however, will be made here to discuss in detail this phase of the subject, as it has been adequately reviewed in previous publications.⁶ Suffice it to say that, whereas such measures will undoubtedly decrease the incidence of thrombosis, they do not completely prevent its occurrence. Even the use of anticoagulants such as heparin and dicumarol have not been found completely satisfactory. Heparin has the disadvantages of being costly, requiring continuous or repeated intravenous injections and maintaining a constant anticoagulant effect with difficulty. Moreover, cases of pulmonary embolism during heparinization have been observed. Dicumarol, which is still in the experimental stage, also has distinct disadvantages. In view of the wide variations in susceptibility to the drug in different patients, the definite danger of hemorrhage associated with its use and the lack of conclusive evidence of its effectiveness for the present, dicumarol "cannot be regarded as a safe, efficacious and satisfactory prophylactic or therapeutic agent in intravascular thrombosis."⁸ Whereas anticoagulants will prevent blood coagulation, their routine use prophylactically is not justified except possibly in the unusual cases in which there is a thrombosing tendency which can be determined by a history of previous thrombosis or a family history of repeated thromboses. Once a thrombus has formed, the use of anticoagulants will not protect against its detachment even though the blood coagulability is decreased. These realistic considerations permit comprehension of the rationale of prophylactic therapy of pulmonary embolism once intravascular thrombosis has occurred. Accordingly the direction of attack must be focused on the prevention of fragments of the thrombus from reaching the pulmonary vascular channels. Obviously the logical means of doing this is by blocking or ligating the venous channel central to the site of the thrombus.

That the value of proximal venous ligation in intravascular thrombosis has long been realized is shown by its interesting historical development. One of the earliest observers to realize the rationale of this procedure was Hunter,⁹ who in 1793 successfully applied it clinically. However, Hunter apparently did not actually perform venous ligation but attempted to accomplish the same purpose by placing compression "upon the part of the vein just above the suppuration." Lee¹⁰ in 1865 was possibly one of the earliest actually to ligate a vein above the thrombotic process. Approximately two decades later Kraussold¹¹ recorded the successful ligation of the femoral vein in a patient with suppurative thrombophlebitis following thigh amputation, and Zaufal¹² reported the successful ligation of the internal jugular vein in the treatment of pyemia originating in the internal ear. Apparently Freund¹³ was one of the earliest surgeons to apply

the method in gynecology. Although the procedures were unsuccessful in preventing a fatal termination, he performed in 1898 ligation and excision of the thrombosed ovarian vein and broad ligament in 2 cases. Perhaps Trendelenburg¹⁴ in 1902 was the first to perform the procedure successfully in a case of puerperal infection. At the first operation he ligated the hypogastric vein, but because the patient continued to have chills he performed a second operation and ligated the ovarian veins. Of interest in this connection is the fact that at this time Trendelenburg expressed the opinion that vena caval ligation should not be considered in these cases because with such extensive thrombosis the procedure would be futile. Nine years later Trendelenburg¹⁵ had apparently changed his mind, as he reported probably the first successful case of vena caval ligation for intravascular thrombosis. Subsequently the procedure was performed by a number of surgeons, as demonstrated by the collected series of 48 cases reported by Krotoski¹⁶ in 1937. More recently Collins and his associates¹⁷ at Tulane University have emphasized its value in suppurative pelvic thrombophlebitis. Ample evidence of the value of proximal venous ligation in intravascular thrombosis has been recorded by numerous other recent reports, which have been reviewed in a previous publication.¹⁸

Whereas it is now generally agreed that proximal venous ligation is definitive therapy in the prevention of pulmonary embolism, its practical application has been difficult. This is due to the frequent absence of precise criteria in determining or in predicting the possible occurrence of embolism. For this reason, some¹⁹ have advocated routine division of the femoral vein in all patients who have or are suspected of having thrombophlebitis of the deep veins of the lower leg. This attitude may be questioned, for certainly pulmonary embolism infrequently occurs in thrombophlebitis and, when found, as we have previously emphasized, is due to the dislodgment of a coagulation thrombus proximal to the thrombophlebitic segment or to the liquefaction of the clot in suppurative thrombophlebitis. The clot resulting from the inflammatory reaction of the veins in thrombophlebitis is firmly attached to the vein wall and does not become loosened to form an embolus. Unless measures are taken to prevent it, however, a red clot or coagulation thrombus can develop in the vein proximal to the fixed white thrombus where stasis is likely to occur. In such an instance detachment of the red thrombus is possible, but this development can and should be prevented as soon as the thrombophlebitic process is detected.

On the other hand in intravenous clotting unassociated with inflammation of the vein, that is, phlebothrombosis, the clot is of the coagulation variety and is loosely attached to the vein wall, permitting its being loosened easily with the development of embolism.

Patients with thrombophlebitis have definite clinical manifestations such as fever, pain and swelling of the involved extremity whereas in patients with phlebothrombosis the symptoms and signs are minimal. As previously emphasized,¹⁸ they may have a sense of impending disaster, exhibit a pulse rate out of proportion to anything else and have tenderness over the involved vein. The frequency of the occurrence of venous thrombosis is clearly demonstrated by numerous recent clinical and experimental investigations. Thus Rocesse²⁰ in careful autopsies of 324 consecutive cases found that thrombosis had occurred in the deep veins of the calf in 88 persons over 20 years of age. Of this number 38 also had thrombosis in the femoral vein, in 10 of whom death was due to massive pulmonary embolism. Neumann,²¹ in a similar study of 165 unslected patients dying from a variety of causes found thrombosis in 100. In 45 per cent thrombosis was present in the veins of the thigh with evidence of extension from a more distal process. Of the cases with thrombosis, 12 per cent showed massive pulmonary embolism and an additional 34 per cent showed multiple nonfatal emboli. Somewhat similar observations have been made by Bauer,²² Hunter and his collaborators,²³ Frykholm²⁴ and others.

These and other reports emphasize the high incidence of the thromboembolic phenomenon and its treacherous nature. The latter feature is illustrated by the fact that frequently the first indication clinically of thrombosis is pulmonary infarction and too often this is fatal. This is especially likely to occur in certain forms of thrombosis. In previous publications we⁶ have distinguished between two major types of intravascular thrombosis, namely, thrombophlebitis and phlebothrombosis. In the former the clotting is believed to be the result of injury to the vascular endothelium from mechanical trauma, bacterial invasion or chemical injury, whereas in the latter it may be due to venous stasis and to alterations in the cellular and fluid constituents of the blood that increase the clotting tendency. The clinical significance of this distinction lies in the fact that in thrombophlebitis the clot is usually firmly adherent to the vein wall and is therefore less likely to become detached and to result in embolism. In phlebothrombosis, on the other hand, the thrombus is loosely attached to the vessel and is more likely to cause embolism. Of particular importance also is the more insidious development of phlebothrombosis, and the frequent lack of indicative clinical manifestations of thrombophlebitis, i.e. pain, fever and swelling, are much less pronounced in phlebothrombosis and not infrequently even absent. The patient does not appear so sick in phlebothrombosis as in thrombophlebitis, but restlessness and anxiety in the former are frequently present. For these reasons a precise method of diagnosis of intravascular thrombosis is desirable. Herein lies the importance of phlebography. Much credit is due dos Santos²⁵ and his son for developing this procedure and directing

attention to its significance. Subsequently Bauer²⁶ elaborated the technique and emphasized further its value. Since then others²⁷ have presented further critical evaluation of the procedure and substantiated its value.

The technique of phlebography is so simple that it can be done easily by any one. Moreover, it is a relatively safe procedure. Although untoward effects of diodrast have been reported,²⁸ we believe that if used properly these can be prevented. The patient is placed on the x-ray table on his back with a 7 by 17 film under his leg and lower thigh. This should be placed so that the popliteal vein will be well visualized on the upper part of the film. A tourniquet is applied to the thigh just below the fossa ovalis and just tight enough to occlude the superficial circulation. This is done in order to shunt the contrast medium from the superficial veins into the deep veins. The leg and thigh are internally rotated in order to separate the shadows of the tibia and fibula and secure unobstructed visualization of the veins (fig 1). Twenty cc of 35 per cent diodrast solution is injected into any vein on the dorsum of the foot or ankle at the rate of 1 cc per second. Twenty seconds after the injection

Fig. 1—Diagrammatic drawing showing the position of the extremity during phlebography. The extremity is rotated medially to separate the shadows of the tibia and fibula. With the tourniquet placed high on the thigh tightly enough to compress the superficial veins, 25 cc of 35 per cent diodrast solution is injected into a dorsal vein of the foot.

is completed the film is exposed. If the standard supporting the x-ray tube is high enough to permit the tube to be 6 feet above the film, visualization of almost the entire lower extremity with one exposure will be feasible (fig 2). In such an instance a 7 by 17 film is placed under the leg and knee and a 14 by 17 film is placed above this under the thigh. The injection of the contrast medium is made in a similar manner, except that 25 cc of diodrast solution is injected and the exposure is made approximately thirty seconds after completion of the injection. Occasionally the veins on the dorsum of the foot may be so small that placing a needle into one is impossible. In such instances the external saphenous which is constantly present just behind the external malleolus, is easily found and cannulated.

If the side of involvement is unknown a single 14 by 17 film is placed behind both legs and lower thighs and injections are made simultaneously into a dorsal vein on each foot. In this way phlebograms of both

legs and popliteal areas can be obtained at the same time.

Normally both the deep and the superficial veins of the leg and thigh fill with the contrast substance and are clearly delineated on the film. Incomplete or irregular filling or absence of filling is an indication of thrombosis. If the deep veins are thrombosed, the superficial veins fill and are dilated. We have observed as have dos Santos²⁸ and Starr, Frank and Fine,²⁹ that resistance to injection, indicative of increased venous pressure above that expected with a tourniquet at the thigh, is present in cases of thrombosis. If a defect in the venous system is visualized, indicating the presence of a thrombus, steps should be taken immediately to prevent its detachment, either by ligating the vein above the site of the thrombus or by removing the thrombus. The latter method is preferred in cases in which the thrombus is in the femoral and extends into the iliacs.

REPORT OF CASES

CASE 1—Mrs H. C., aged 44, white, seven months pregnant, went into labor with breech presentation. Cramiotomy was necessary for delivery. The postpartum course was so uneventful that she was discharged on the sixth day. She remained in bed at home and on awakening on the morning of the eleventh day noted that her left leg was swollen considerably, ashen in color and painful to touch, especially in the calf. She returned to the hospital, where it was found that her temperature was 99.1° and pulse rate 90. There was considerable edema of the leg and thigh with tenderness in the calf and along the course of the femoral vein. Phlebothrombosis was suspected and confirmed by phlebography, which showed that the entire deep venous system was obliterated. Exploration of the femoral vein revealed a typical "red thrombus," which was aspirated from the vein both proximally and distally. Bleeding occurred from both ends of the vessel after aspiration of the clot. The vein was

ligated between the entrance of the vein profunda and the internal saphenous.

The patient remained without further symptoms after the ligation.

Lawen,³⁰ Kulenkampff,³¹ Lange, Frund³² and others have advocated various types of thrombectomy in the treatment of these cases. If a defect in the superficial venous system, the deep system or both is visualized, immediate operation should be done in order either to ligate the involved

Fig. 2—Diagram showing the method of visualization of the venous system of the entire lower extremity with one exposure. By employing a tube-film distance of 6 feet in which parallel rays will reach the film it is possible, with two films placed in tandem to visualize the venous system of the entire lower extremity.

vein above the thrombus or to remove the clot and ligate the vein, so that detachment of the clot with the development of embolism can be prevented. There is usually some edema and cyanosis of the extremity following ligation, which responds well to procaine hydrochloride sympathetic block and elevation. The

tenderness over the thrombosed veins remains for a week or ten days and then subsides. There is usually a slight rise in temperature for a few days postoperatively.

CASE 2—Mrs M C, aged 59 white admitted to the surgical service, complained of a recurrent left femoral hernia which had been repaired three years previously only to recur three weeks prior to admission. With the exception of the hernia and moderate obesity, the physical examination and complete laboratory work-up were normal for a person of her age. A rather extensive hernia was repaired and the postoperative course was uneventful and afebrile until the seventh day. At this time an unaccountable fever occurred which persisted for two days. On the ninth postoperative day she complained of pain in the left heel. Tenderness was noted on pressure in the left calf, and pain was present in the calf on dorsiflexion of the foot. There was no swelling or discoloration of the extremity. Phlebotrombosis was suspected, and phlebography revealed the presence of a clot in the deep veins of the leg (fig 3). Ligation of the femoral vein was done immediately distal to the internal

Fig. 3—Phlebogram in case 2 showing normal filling of the dilated superficial veins of the upper leg and the deep and superficial veins of the thigh but an absence of filling of the deep veins of the leg indicating the presence of a clot in this area.

saphenous. We believe, contrary to the opinion of Fine and his co-workers, who prefer to ligate just distal to the vena profunda, that generally all of the deep circulation should be occluded.

CASE 3—A G, a white man aged 59, was admitted to the hospital following a crushing injury in which he sustained a simple fracture of the right femur and fibula. Physical examination and laboratory studies were otherwise normal. The fracture was reduced by traction with a Steinmann pin inserted through the upper tibia, and a spica cast was applied. Three days later he developed sudden severe chest pain, fever to 103 F

and a pulse rate of 160. Examination and a portable chest x-ray film gave evidence of a pneumonic process at the right base. He was treated unsuccessfully with sulfathiazole and specific type vii pneumococcus serum for eleven days. At this time he again had sudden severe chest pain with elevation of pulse and temperature and pronounced dyspnea. He also com-

Fig. 4—Phlebogram in case 3 showing filling of the deep and superficial veins of the leg, popliteal area and lower thigh with a defect in the deep veins of the midthigh.

plained for the first time of pain in the right thigh. Phlebotrombosis was suspected. The cast was removed and a phlebogram made (fig 4). A defect was visualized in the femoral vein, and ligation was done. Since this time he has been afebrile and has had a normal pulse and no respiratory symptoms or signs.

It is obvious, then, that this patient had phlebotrombosis and two attacks of pulmonary infarction. This case illustrates that not all pulmonary infarctions are fatal. Even though almost three fourths of the patients with pulmonary embolism survive, the fact that in 30 per cent of patients the embolism is massive enough to be fatal emphasizes the potential gravity of every case of phlebotrombosis.

CASE 4—Interestingly enough this patient also had pulmonary infarction, which was treated originally as a pneumonia. O D a Negro woman aged 29 was admitted to the gynecology ser-

Fig. 5—Bilateral phlebogram in case 4. On the right side there is normal filling of the superficial and deep veins, whereas on the left there is an absence of filling of the deep veins. Because of blockage of the deep veins the superficial veins are abnormally prominent.

vice complaining of right lower quadrant pain. She was treated conservatively for pelvic inflammatory disease and discharged eleven days later with instructions to remain in bed at home. She returned four days later stating that two days after being home she had sudden severe sharp pain in the right chest and

difficulty in breathing. A physician was called who prescribed therapy without relief and advised hospitalization. The admission diagnosis was pneumonia because signs of consolidation were found at the right base and there was x-ray evidence of pneumonia. In light of subsequent findings this is now interpreted as an infarction. She recovered completely except for fluoroscopic evidence of thickened pleura and impaired diaphragm-

Fig. 6—Bilateral phlebograms in case 5. On the right side there is normal filling of both the deep and superficial veins, whereas on the left there is an absence of filling of the deep veins and also dilatation of the superficial veins indicating a thrombus in the deep venous system.

matic function noted eight days later. She was discharged after nineteen days in the hospital. She returned five days later to the gynecology service stating that for the past few days she had pain in the left thigh. This is the first time any complaint of any difficulty in the lower extremities could be found. Examination revealed moderate edema of the left leg and thigh with tenderness over the femoral vein and in the calf. A diagnosis of phlebothrombosis was made because the patient was relatively afebrile. Phlebograms were made which show normal filling of the right femoral, absence of the left femoral and presence of superficial left thigh veins (fig. 5). Because of the

Fig. 7—Phlebogram in case 6 showing well filled long sphenous vein and dilatation of other superficial veins but absence of filling of the femoral, indicating the presence of a thrombus in the deep venous system.

previous infarction, the femoral vein was explored and found to contain a typical "red thrombus".

This case illustrates, how in many cases repeated nonfatal embolisms can occur. Fortunately, in spite of the delay in recognizing the true condition the infarctions were relatively small and the involved vein

was finally ligated before an embolism large enough to cause death broke loose.

CASE 5—Mrs. A. L., aged 22, white, was admitted to the obstetric service near term with preeclamptic toxemia. She delivered two weeks after admission and was then transferred to the medical service for study because of a pronounced anemia. While there she developed a typical thrombophlebitis of the right lower extremity for which procaine sympathetic lumbar block was done on several occasions. Six days later, because of progression of her symptoms, consisting of increasing pyrexia and swelling, phlebograms were done which showed obliteration of the right femoral vein but a normal left femoral vein (fig. 6). Because of considerable pelvic tenderness it was thought by the gynecologists that she had a pelvic thrombophlebitis, which was proved at operation. The inferior vena caval and the ovarian veins were ligated. The temperature returned to normal within ten days.

CASE 6—Mrs. L. H., aged 23, white, was admitted to the gynecologic service complaining of flooding. A diagnosis of cervical erosion, hyperplastic endometrium and relaxed perineum was made and a dilation and curettage, conization of the cervix and posterior colporrhaphy were done. Postoperatively on the eighth day she developed fever, which was thought to be due to parametritis. On the twelfth postoperative day she

Fig. 8—Bilateral phlebograms in case 7 showing normal filling of both superficial and deep veins. Although clinically intravenous clotting was suspected, the normal filling of the veins, as demonstrated by phlebography, ruled out the presence of an intravenous clot. Patient's symptoms were subsequently found to be due to a cul de sac abscess.

complained of pain in the left thigh. It was noted that there was mild edema of the thigh and leg and tenderness along the course of the femoral vein. Phlebographic studies showed a complete femoroiliac obliteration (fig. 7). Repeated lumbar sympathetic procaine blocks relieved the clinical manifestations of thrombophlebitis.

In cases of thrombophlebitis, ligation is unnecessary because here the clot is intimately attached to the vein wall and embolic phenomena rarely if ever occur.

CASE 7—Mrs. L. H., aged 43, white, on her second postoperative day following a hysterectomy developed fever to 104 F., the pulse rate was 110. This persisted until the fifth day, when slight edema of the legs was noted. Pelvic or iliofemoral thrombophlebitis was suspected, and phlebograms were made. The deep veins were found to be normal (fig. 8). Subsequently an abscess was detected in the cul-de-sac and drained resulting in relief of symptoms.

Thus it is demonstrated that often negative phlebograms are of considerable aid.

CASE 8—Mrs. M. McI., aged 55, white, developed left thrombophlebitis following an injury resulting in excision and laceration of the colon. Phlebography demonstrated obliteration of the deep veins and dilatation of many superficial veins (fig. 9).

Although phlebography demonstrated very clearly in this case the extent of the thrombophlebitic process we believe that this procedure is generally not necessary in thrombophlebitis in contradistinction to phlebotrombosis, in which accurate localization of the clot is essential in order that adequate therapy may be instituted

CASE 9—S G, a Negro woman aged 43, had an extensive carcinoma of the cervix. She had a definite internal sphenous thrombophlebitis and was suspected of having deep venous thrombosis. Phlebography, however, demonstrated a patent femoral vein (fig 10)

In superficial thrombosis the diagnosis is usually obvious because the vein is readily palpable and often visible. There is inflammatory reaction and tenderness along its course. Whereas embolism seldom follows thrombophlebitis of the superficial veins, it can complicate phlebotrombosis of this system. Because

Fig 9—Phlebogram in case 8 showing complete absence of filling of the deep venous system with filling and dilatation of the superficial veins. In this case the intravenous clot was the result of thrombophlebitis and not phlebotrombosis.

of the innocuousness of and the ease with which ligation of the superficial veins can be done, it is indicated in all spontaneous intravenous clotting of the superficial veins of the thigh.

CASE 10—M J, a Negro woman aged 45 had a vaginal hysterectomy. The postoperative course was stormy because of pelvic peritonitis and a thrombophlebitis in the right iliofemoral vein was suspected. Lumbar sympathetic nerve blocks were done and apparently the thrombophlebitis cleared up. The pelvic infection improved and she was discharged. She returned with swelling of the leg and tenderness of the calf on the right side. Bilateral phlebography showed normal veins on the left and occlusion of the deep veins of the right leg with apparently a long clot extending into the popliteal and femoral veins (fig 11). Another phlebogram taken an hour later showed the same defect (fig 12). Because the filling defect in the popliteal and femoral veins was incomplete it was thought that the thrombus was lying loose in the vessel and therefore was even more likely to become detached than those in most cases of phlebotrombosis. Operation was considered even more urgent

in this case than usual. At operation a long red thrombus was sucked from the vein and ligation was done at the site of election.

This patient had not suffered embolic disturbances, but one can readily see what might have happened if the vein had not been ligated.

Fig 10—Phlebogram in case 9. Although a deep vein thrombosis was suspected phlebography showed satisfactory filling of the deep veins but in absence of filling of the superficial veins indicating a thrombus in the long saphenous.

CASE 11—C J K, aged 60 was seen at his home on Jan 15, 1942 with the story that approximately five weeks previously he had developed pneumonia. He was treated by the usual

Fig 11—Bilateral phlebogram in case 10. On the left there is normal filling of both the deep and superficial veins whereas on the right there is filling of the deep veins of the thigh and the superficial veins of the leg but a defect of the deep veins of the leg and popliteal vein. The defect produced by the clot extending up into the saphenous can be well visualized.

methods and recovery was quite satisfactory except that he continued to have a rapid pulse subsequently. He developed another attack of pneumonia on the opposite side. This was associated with hemoptysis. Not until two more attacks had

occurred was it evident that the pulmonary lesion was infarction. Heparin was administered and blood coagulation varied between fifteen minutes and one hour. During the period of heparinization which lasted approximately ten days, two more emboli broke off. At the time he was extremely ill semicon-

scious and cyanotic in spite of the fact that he was in an oxygen tent. Careful examination failed to reveal any evidence of thrombosis. The patient was removed to the hospital. Bilateral phlebography was done by inserting a cannula into a dorsal vein on the dorsum of each foot, 125 cc of diodrast was injected into each foot simultaneously and an x-ray exposure was placed under the thigh and another 125 cc of diodrast was injected into the foot, x-ray exposures of the thigh being made. Examination of the phlebograms showed filling of all the veins except the short saphenous on the left (figs 13 and 14). The patient was taken to the operating room immediately and the upper end of the short saphenous vein was exposed. It was found to be collapsed and dissection down for a short distance disclosed that it was completely empty. Because of the poor condition of the patient it was decided not to extend the incision down until the thrombus was reached, but instead the vein was tied off. The extremities were wrapped with compression bandages from the toes to the groin, and active mobilization was started. Because of extensive pneumonitis he was given sulfonamides, which gradually brought down his temperature. His progress was uneventful from there on.

CONCLUSIONS

- 1 Phlebography is imperative in all cases of intravenous thrombosis in which the clot is not firmly attached to the vein wall, i e., in phlebothrombosis.
- 2 The procedure is simple, safe and informative.
- 3 Whenever in phlebothrombosis a defect in the venous system is demonstrated immediate operation

Fig 12—Phlebogram of the right leg in case 10 demonstrating normal filling of the superficial veins with dilatation of these veins of the calf but absence of filling of the deep veins of the leg and popliteal area with the defect extending up into the femoral

scious and cyanotic in spite of the fact that he was in an oxygen tent. Careful examination failed to reveal any evidence of thrombosis. The patient was removed to the hospital. Bilateral

Fig 13—Bilateral phlebograms in case 11. There is satisfactory filling of the deep and superficial veins of the popliteal area and the thigh demonstrating an absence of clot in these areas.

phlebography was done by inserting a cannula into a dorsal vein on the dorsum of each foot, 125 cc of diodrast was injected into each foot simultaneously and an x-ray exposure was placed under the thigh and another 125 cc of diodrast was injected into the foot, x-ray exposures of the thigh being made. Examination of the phlebograms showed filling of all the veins except the short saphenous on the left (figs 13 and 14). The patient was taken to the operating room immediately and the upper end of the short saphenous vein was exposed. It was found to be collapsed and dissection down for a short distance disclosed that it was completely empty. Because of the poor condition of the patient it was decided not to extend the incision down until the thrombus was reached, but instead the vein was tied off. The extremities were wrapped with compression bandages from the toes to the groin, and active mobilization was started. Because of extensive pneumonitis he was given sulfonamides, which gradually brought down his temperature. His progress was uneventful from there on.

Fig 14—Bilateral phlebograms of the leg in case 11. On the right side there is normal filling of the superficial and deep veins. On the left however there is an absence of filling of the short saphenous in its lower portion indicating a thrombus in this area which was demonstrated at operation.

is imperative. This should consist of either ligation of the involved vein above the site of the thrombus or thrombectomy.

- 4 Only by the prompt recognition of intravenous thrombosis in phlebothrombosis and the institution of measures to prevent the detachment of the clot can the mortality rate from pulmonary embolism be decreased.

Iron Used as Medicine—Iron has been used as a medicine since ancient times. Dioskorides gave iron rust to women who were flooding. Water or wine in which a glowing piece of iron had been quenched was long used as a treatment for diarrhea and dysenteries. As one would expect, iron was used often for exorcising disease. A curious idea was that of the Romans, who drove nails into the walls of the temple of Jupiter in order to ward off epidemics. Perhaps with some what similar ideas the Germans in the last war drove nail into a wooden bust of Bismarck.—Alvarez, Walter C., in *Essays in Biology*, Berkeley, University of California Press 1943.

LESIONS OF THE ESOPHAGUS IN GENERALIZED PROGRESSIVE SCLERODERMA

JOHN R LINDSAY, MD
FREDERIC E TEMPLETON, MD
AND
STEPHEN ROTHMAN, MD
CHICAGO

Generalized or diffuse scleroderma is a disease well studied from the clinical and the microscopic point of view and certainly is a well defined clinical entity. It is not restricted to the skin and to the organs adjacent to the skin but is a generalized systemic disease of the connective tissue.

In most cases the process starts on the hands and feet with a somewhat later and slower involvement of the face.

Three stages can be distinguished clinically: the edematous, the indurative and the atrophic stage. The initial edema does not pit on pressure. The skin appears tense and cannot be folded. The face assumes a mask-like expression, the regular folds smooth out. In the second phase the skin hardens and stiffens. This is particularly pronounced on the fingers, on the dorsa of the hands and in the region of the ankles. Hyperpigmented and depigmented spots appear in this stage. In the third stage the tips of the fingers become smaller and pointed, and the fingers are immobilized in a flexed position. The face, the nose, the ears, and the lips become gradually smaller and thinner. Ectropion develops in consequence of the atrophy of the lids. All mucous membranes of the mouth (tongue, hard and soft palate and gums) may be involved in the indurative and atrophic process. Ulcers, probably due to tension and deficient circulation, develop mainly on the finger tips, the elbows and the ankles. Fibrosis of the lungs without any subjective symptoms is a common sign of the disease.

With regard to the initial signs, two types of the disease can be distinguished: the type starting with Raynaud-like signs and symptoms and the arthritic type, the latter starting with joint pains and stiffness because of primary scleroderma in the articulations. There are condensation and absorption of bone material and atrophy at the joint surfaces with rarefaction of the substantia spongiosa. However, these two types are often intermingled. In the arthritic type one may see acroasphyxia of the fingers at any time, and in the Raynaud type severe arthritis may develop. Calcium deposits in soft tissues are often recorded, and true calcinosis in combination with scleroderma was described as a special syndrome by Thibierge and Weissenbach.

Pathologically, the main feature of the disease is a peculiar change of the collagenous tissue usually designated as homogenization. After the edematous stage with the picture of swollen and loose fibers, the collagenous fibrillae become thickened and less acidophilic than normal or even basophilic, which means that the collagen assumes acid properties. In this dense fibrous connective tissue the fibroblasts are shrunken and less numerous than normal. The vessels are intensely involved by the fibrotic process.

The muscularis is completely replaced by connective tissue consisting of gross fibers. Also the elastica may disappear completely.

LESIONS OF THE ESOPHAGUS IN GENERALIZED SCLERODERMA

Up to the present time little attention has been paid to the disturbance of esophageal function in diffuse scleroderma although it seems to be present in many cases and may be an early sign.

Difficulty in swallowing has been reported in 16 cases of diffuse scleroderma. A postmortem examination of the esophagus has been made in 3 cases, while an esophagoscopy examination made during life has been reported in only 1. No microscopic examination made during life has been reported.

In 1932 Fessler and Pohl¹ reported esophagoscopy findings in a single case. The mucosa down to a stricture at a depth of 32 cm was normal. The stricture appeared to be dense scar tissue narrowing the lumen so that a thin probe could not be passed. Although the mucosa in the stenosed part bled slightly, no gross ulceration or tumor was seen, and the firmness of the scar ruled out the possibility of spasm.

Ken Kure and his associates² described the microscopic changes in the esophagus of a patient examined post mortem as "dystrophic."

In 1931 Rake³ described gross and microscopic postmortem findings in a case of scleroderma in which the roentgenologist had described contraction in the lower end of the esophagus six years earlier. Grossly the esophagus was dilated to 4.5 to 5 cm in width. The muscular coats were not visibly hypertrophied, but the mucosa was absent over the lower three fifths of the organ. The author did not state whether or not the patient had free acid in the stomach, so it is not known whether or not the loss of mucosa was the result of postmortem degeneration, peptic esophagitis or scleroderma. In the upper third erosions were present in an intact mucosa, but in the middle and lower thirds the mucosa was lacking. The submucosa was thickened and infiltrated with cells which were chiefly mononuclears with a few polymorphonuclear leukocytes; the changes were more extensive in the lower two thirds. Auerbach's intermuscular plexus was intact, and the ganglions and muscles appeared normal. A diagnosis of chronic ulcerative esophagitis was made.

Roentgenologic examinations of the esophagus have been made in 13 of the 16 reported cases. The descriptions have been somewhat sketchy. However, those given by Fessler and Pohl, Ken Kure and Weissenbach and his co-workers⁴ have been fairly detailed. All of these authors described diffuse dilatation of the esophagus with the passage of the bolus slowed, especially when the patient was in the horizontal position. Hoelsi⁵ presented a case in which the retardation of the bolus was noticed only at the cardia. Weissenbach and Fessler and Pohl¹ reported regional stenosis in the lower end of the esophagus. Fessler and Pohl also reviewed the

literature and found that the lesions in the esophagus had been termed cardiospasm (Nomland), esophagitis (Schwarz), diverticulum (Fihmann) and atony (Schmidt)

All of the 5 cases which form the basis of this report were clinically and histologically typical cases of diffuse

Fig. 1 (case 1)—On the left barium sulfate fills the lower end of the esophagus, showing the stenosis (arrow) at the upper border of the phrenic ampulla. On the right air is seen in the esophagus after most of the barium sulfate has passed through.

scleroderma. The patients were 3 men and 2 women. They presented clinical evidence of a disturbance of the swallowing mechanism, varying apparently only in the stage of the esophageal lesion. There was roentgenologic evidence of disturbed function of the esophagus in all 5 with a varying degree of stenosis in 3. Four of the patients were examined on one or more occasions by means of the esophagoscope, and biopsy was performed in 2 cases.

CASE HISTORIES AND SYMPTOMATOLOGY

Considerable variation in the severity and the time of onset of esophageal symptoms seems to be characteristic.

Only 1 of the 5 patients volunteered any complaints referable to swallowing. In the other 4 the symptoms were clearly brought out on questioning, but the comparative severity of the pain and discomfort from the cutaneous lesions caused the difficulty in swallowing to be overlooked.

In the first patient (S S), an unemployed man aged 40, the difficulty in swallowing preceded the complaints referable to the skin by one and a half years. The obstruction was apparently steadily progressive for seven years. Dilation had been done five years previously and repeated at irregular intervals. He had not complained of epigastric pain at any time. When first seen he was receiving feedings through a gastrostomy opening, with a string in the esophagus for retrograde dilation. At admission he displayed fully developed, easily recognizable generalized scleroderma with the characteristically stiff and atrophic appearance of the face and the hands. He gave a typical history of initial Raynaud-like signs and symptoms occurring five and a half years ago.

The second patient (J F), a man 48 years old, had suffered from generalized scleroderma for three years. He was under

the observation of the dermatology clinic of the University of Chicago for two and a half years. During this period he had an "arthritic" syndrome with typical sclerodermatic bone changes, Raynaud-like signs and symptoms, and severe ulceration on the finger tips, the elbows and the ankles. Thoracic sympathectomy was performed, but the operation had no beneficial effect whatever. His cutaneous disorder was clinically and histologically typical for scleroderma. On being questioned he admitted that he had had difficulty in swallowing. Solid food in particular seemed to stick and cause a fulness in the lower sternal region. The lower part of the esophagus was already stenosed to a diameter of about 6 mm.

The third patient (N S), a milkman aged 46, had noted numbness of fingers and hands to cold for about eighteen months. On admission he did not have typical scleroderma, but the shape and the pigmentary anomalies of the fingers and some spotted shiny areas on the upper part of the chest aroused suspicion. Neither solid edema nor atrophy was seen. However, in the course of one month's hospitalization there was progressive stiffening of the fingers, the dorsa of the hands and the chest. At a few spots definite signs of atrophy were seen. Microscopic examination of the skin revealed characteristic histologic changes. The patient also gave a history of pain beneath the sternum and in the epigastrium beginning eighteen months earlier. Pain came on about an hour after taking food, especially after consuming beer, "soda pop" and "hot dogs." It gradually became more frequent, lasted longer and was worse on lying down also on vomiting and bowel movements. A preparation containing chiefly magnesium carbonate and sodium bicarbonate or one designated as citrocarbonate gave relief.

The difficulty with cold hands was noticed about six months after the digestive complaints. Although the burning pain was always located behind the sternum from the epigastrium to the neck, it had been interpreted as due to gastric ulcer, until a review of the history and x-ray examination of the esophagus as well as an esophagoscopy were made. At this time an early degree of stenosis at the lower end of the esophagus was present.

The 2 women presented a less advanced symptom complex referable to the esophagus. The first of these (M G, aged 54) had had scleroderma for fifteen years and had been observed in the dermatology outpatient department for thirteen years; she had experienced difficulty in swallowing for over two years. Water was the worst offender and had to be swallowed slowly. A spasm of coughing frequently followed and there was a sensation of fullness for a few moments behind the sternum, more noticeable and prolonged on lying down. The patient had found that she had great difficulty in swallowing water while lying down.

The second (I N, aged 54), with scleroderma for six and a half years, which on admission extended over the whole body and face, gave a history of dysphagia on careful questioning.

Fig. 2 (case 2)—Patient in horizontal position. The esophagus remains dilated throughout. A moderate degree of stenosis (arrow) was present at the upper border of the ampulla.

6 The term acrosclerosis has not been used in this paper although all of our 5 cases fit the description of acrosclerosis given by J. Seller (Die Akrosklerose [Sklerodaktylie] und deren Symptomenkomplex, nebst neueren Untersuchungen bei Sklerodermie, Arch. f. Dermat. u. Syph. 163 343 365, 1931) and that by P. A. O'Leary and M. Waisman (Acrosclerosis, Arch. Dermat. & Syph. 47 382 397 (March) 1943). We felt that what has been designated as acrosclerosis is identical with what always has been called diffuse or generalized scleroderma with sclerodactylia.

ing For over two years she had noticed heartburn a dull pain behind the sternum extending up to the neck an hour or so after eating occasionally was present in daytime but was more annoying at night On drinking a glass of water she had to stop and wait a few moments for it to go down A sensation of a load on her chest followed the drinking of a few mouthfuls, which she compared to the weight of "holding a baby in her

Fig 3 (case 3)—Two views of barium sulfate in the lower end of the esophagus showing moderate stenosis (arrows) at the upper border of the ampulla

arms' and which required a few moments to pass off On testing her ability to drink a glass of water while in the reclining position she had much difficulty in getting down more than a few sips She had noticed that lying on her left side would bring on the burning pain beneath the sternum"

RESULTS OF FLUOROSCOPY

On fluoroscopy each of the 3 men was found to have a localized narrowing of the esophagus about 4 or 5 cm above the level of the diaphragm (figs 1, 2 and 3) The narrowing was abrupt, measuring 2 or 3 cm in length and varying in width Some variation in width occurred with distention of the esophagus and with pulsation of the heart

In all 5 patients there were pronounced changes in the muscular movements⁸ With the patient standing, barium sulfate passed from the pharynx to the stomach with some delay at the site of stricture but not at the cardia When the patient was placed in the horizontal position the barium sulfate entered the esophagus and

7 A sixth patient with generalized scleroderma (a patient of Drs Oppenheim and Cohen Chicago) did not volunteer complaints referable to the esophagus He had difficulty in swallowing in that fluids sometimes escaped up into the nasopharynx and the nose apparently because of stiffness of the soft palate Fluoroscopic and x-ray examination revealed complete absence of primary secondary and nearly all tertiary peristaltic waves of the esophagus Esophagoscopy showed no exudate or ulceration of the esophageal lining This apparently represents an early stage of the disease affecting the esophagus

8 Physiologists describe three types of muscular activity in the esophagus namely the primary secondary and tertiary waves The primary wave is initiated by the act of deglutition and begins in the pharynx As it progresses down the esophagus a wave of inhibition precedes the wave of contraction so that the esophagus distends as the bolus is forced along As the wave of contraction passes the esophagus and larynx down as if to move his bowels after swallowing a bolus of a barium sulfate mixture the closure of the cardia probably produced by the punchcock action of the diaphragm offers resistance to the passage of the bolus The 1 or 4 centimeters of the esophagus above the larynx becomes considerably distended The primary peristaltic wave continues to hold his breath barium sulfate will regurgitate up the esophagus through a narrowing when the esophagus above relaxes This narrowing is seen only during the phase of regurgitation and not during the forward movement of the bolus

Secondary waves are similar to primary waves except that they originate in the middle of the esophagus usually at the level of the aortic arch Tertiary contractions are not clearly understood and are sometimes called cutting They appear as irregular contractions of the lower half of the esophagus and last for not more than a second or two At the height of the contraction the esophagus has a beaded appearance

there remained As each successive bolus was taken the esophagus distended to receive it, reaching a width of approximately 4 to 5 cm The primary peristaltic wave which normally arises in the pharynx and travels the length of the esophagus with each act of deglutition traveled only down to about the level of the suprasternal notch In the 3 men and 1 woman the waves ceased entirely, but in the second woman (M G) it continued on down the esophagus as a wave insufficient in depth to propel the bolus along In its progression this shallow wave differed from the normal wave in that the esophagus behind the advancing peristaltic constriction did not remain contracted but distended immediately The shallowness of the wave and the immediate distention of the esophagus behind the advancing wave allowed barium sulfate in the esophagus ahead of the wave to regurgitate through the peristaltic constriction into the esophagus above as the peristaltic wave progressed toward the stomach

The failure of the esophagus below the level of the suprasternal notch to contract efficiently undoubtedly explains the retention of barium sulfate in the esophagus as long as the patient remained in a horizontal position Air which was also taken with the act of deglutition remained in the esophagus If at this stage of the examination the patient was raised to a sitting or a standing position, the bulk of the barium sulfate passed into the stomach, but the esophagus did not collapse completely the walls being separated by air within the lumen (fig 1) It seemed obvious that the emptying of the esophagus was caused by gravity rather than by contraction of the walls and that in the case of the strictures the rapidity of the emptying was slowed only because of the resistance offered by the strictures

While a woman (F N) was in the horizontal position, a small amount of barium sulfate was seen passing into the stomach during each expiration, but during inspiration the cardiac sphincter appeared firmly closed During the Valsalva experiment in this patient, instead of the cardiac sphincter pinching off the esophagus and the phrenic ampulla ballooning out as in the normal person, the cardiac sphincter opened, permitting passage of barium sulfate as a result of the increased intrathoracic pressure (fig 4) The narrowing seen at the upper level of the ampulla in this illustration was not constant and therefore was not interpreted as an early degree of stenosis

Fig 4 (case 5)—This view was taken during the Valsalva maneuver Barium sulfate is seen passing from the ampulla through the cardiac sphincter An apparent narrowing is seen at the upper border of the ampulla but no stenosis was demonstrated

If these patients were allowed to remain in the horizontal position after the esophagus filled and additional

There is a major responsibility involved in every decision that the psychiatrist makes regarding an inductee. For every case he approves for the Army which turns out to be a misfit or a psychiatric casualty, the cost in money and morale is incalculable. We know that the psychiatric casualties of the last war have occupied more beds in veterans' hospitals and have cost more money following discharge than all other cases together. Each man is estimated to have cost approximately \$30,000.⁴ The cost in investment of time and equipment to train a soldier in a fighting unit only to have him break or become a misfit is an undetermined but undoubtedly a large figure. The cost to the unit in morale, particularly if it occurs in combat in a foreign land, is devastating. Equally important is the fact that these men often are indirectly a great loss to the home front. Undoubtedly there are many individuals whose adjustment to life may not have been entirely satisfactory even from their own point of view, but they have been an asset in the community; they have contributed in helpful occupations and if permitted to run their own lives and put in their eight hours a day could maintain their adjustment. When we make the mistake of forcing such a man into the Army with its discipline, its necessarily regimented way of life, its close proximity to people twenty-four hours a day, its many and varied threats, he cannot "take it" and he is not only lost to the community but lost to the Army and to himself.

It is important further that some consideration be given to the men who are turned down by the Army. The Surgeon General's Office issued a letter many months ago directing that every medical officer use the greatest consideration in turning a man down and suggested that advice be given the rejectee as to what help he might obtain. In a few larger communities social agencies are at work⁵ in connection with the draft boards attempting to relocate these men and to provide them with advice and medical help in relation to their course following rejection.

Our great psychiatric problem, then, for the induction center is concerned with the fact that we are raising an immense army at great speed. We lack sufficient psychiatrists to examine the inductees adequately. It is the local draft board's responsibility, and through it every civilian physician, to aid not only in the selection of these men but in supplying medical and social histories about them. The opportunity to aid in the adjustment of the men who are returned by the induction board as unacceptable to the armed forces will also fall to the medical profession.

STATION HOSPITAL

Every civilian who comes into the Army must make radical readjustments and do so promptly if he is to fit into the organization. This adjustment is not easy and the result is that a large percentage of our breakdowns and our misfits, both physical and mental, make their appearance within the first few weeks.⁶ Many

of these men can be salvaged and for this reason in each of our large basic training camps, which are called replacement training centers, there are special training units under the direction of a psychiatrist.⁷ In these training units the individual is given special opportunities to fit into the program at a little slower pace. Many such individuals who fail too flagrantly are discharged at this point in their training. Those who need hospital care or attention are referred to the station hospital, and in the smaller camps and the camps for advanced training the hospital serves as the clearing agency as well as the treatment center.

In our Army hospitals there are two types of problems confronting psychiatrists, administrative and clinical. In many ways these are inseparable and they also apply to every other field of medicine as practiced in the Army.

A major administrative problem confronting every army psychiatrist is the discharge procedure from the Army. Approximately half the soldiers admitted to the neuropsychiatric sections of our hospitals are recognized as being unfit for the Army. These men constitute nearly one third the discharges for all causes. It is the psychiatrist's responsibility not only to study his case and work up the hospital record but to engineer the discharge of the patient. Since different procedures are necessary for officers and enlisted men and different methods of discharge prescribed for different types of psychiatric diagnoses, considerable experience is required to expedite the discharge and the actual disposition of the patient. And, further, each case requires considerable investment of time. This investment of time becomes a major consideration from two angles: the shortage of psychiatrists and the filling of the wards with long-time patients for whom there is little opportunity for rehabilitation as a soldier.

A considerable number of physicians have been assigned to neuropsychiatric sections who have never had either training or special experience in this field, but the shortage of men has made this necessary. This situation is an additional handicap for every one and the lack of familiarity with diagnostic experience often contributes to slowing the disposition of the patient. A constant headache for every army psychiatrist is the arrangement for and actual transfer of his psychotic patients to a civilian or government hospital. The mechanics of this transfer are such that a soldier may in some cases have to remain for months in the army hospital occupying space and time from the medical officer that should be given to the potential soldier who can be rehabilitated for army service.

Because of the geographic nature of this war with the combat zones in foreign lands, special care must be used to eliminate the unstable. Our discharge rate of psychiatric cases might be materially reduced if our induction boards could be adequately staffed with psychiatrists. As the situation now stands, the rate will probably increase. Until the very recent past, too many unstable individuals were undetected and many were kept in the Army on the probably correct assumption that in a relatively protected environment they could function fairly effectively. But there is no guaranty that a relatively protected environment can be provided.

Thomas Jr. of meningococcal meningitis and septicemia in the Fourth Service Command, it was found that twice as many cases of meningitis developed in new troops as occurred in seasoned troops, and the mortality was four times as great in the new troops.

7 Stilwell, L. E., and Schreiber, Julius. Neuropsychiatric Problems for a Replacement Training Center, War Med 2 20 (Jan) 1941.
Holloran, R. D., and Farrell, M. J. Neuropsychiatrists in the U. S. Army: Their Functions in General and in Relation to Replacement Training Centers. Army M Bull 65 151 (Jan) 1943.

In March the War Department reported that too many men who were mentally unsuited for ordinary military duties had arrived overseas and again cautioned that special consideration must be given to eliminating such individuals. Until recently a soldier with a mild psychiatric problem could be placed on "limited duty," that is retained in the Army but not assigned to combat duty, but this classification is now eliminated. Probably necessitated by inadequate psychiatric judgment on the part of many medical officers, a directive has recently been issued that all soldiers in whom a mental diagnosis is made, unless they will be able to return to full duty, are to be definitely eliminated from the Army.

Another administrative problem confronting the army psychiatrist, probably more so than other specialists, is the treatment opportunities⁸ for his patients. This is more of an administrative rather than clinical problem for the reasons that it is a question of time, facilities and assistants. In the army hospital all of these are at a great premium. Furthermore, the Army has as its chief aim the winning of the war. Consequently those individuals who cannot be made into fighting soldiers must be passed on to those established government, state and community agencies for their further care and treatment.

It is not to be construed, however, that treatment efforts are completely lacking in our neuropsychiatric setups. In the replacement training centers, the psychiatrist often spends several hours in psychotherapy with a soldier. In our active consultation and outpatient clinics in the hospital, psychotherapy is widely used. Many of our hospitals are equipped with prolonged immersion tubes and pack beds. The Surgeon General's Office is making plans at the present time for the assignment of available occupational therapists to our army hospitals.

In most of the installations in the Fourth Service Command we have instituted an organized and planned occupation and recreation program, utilizing the aid of the Red Cross workers, nurses and ward attendants. Recently approval has been given for the use of shock therapy by qualified psychiatrists. Partially to solve the problem of too few psychiatrists, group psychotherapy has been used with some success.⁹ In order to increase the effectiveness of these therapeutic efforts the chief of the neuropsychiatric section in many of our hospitals in this command conducts a continuous training course in psychiatry for the nurses, ward attendants, occupational therapist and Red Cross workers.

In the clinical field there are many intriguing problems for the army psychiatrist. Various clinical pictures rarely encountered in civilian practice, present themselves in great numbers. Severe nostalgia is extremely common and is recognized as a clinical entity.¹⁰ Enuresis in the adult is a common problem in the Army,¹¹ much more so than any one might have suspected. Somnambulism, particularly in the Navy, is

often a psychiatric problem, true malingering is probably rare, although except for special cases of compensation neurosis it is frequent in comparison with civilian practice.

Among the more severe mental reactions anxiety attacks are most common. The anxiety is often acute though not attached to specific ideas. Sometimes it is expressed in specific fears, undoubtedly it is often expressed in the form of somatic complaints. The most common acute psychotic episodes are schizophrenic in character. A special feature of many cases of this last type of illness has been the extremely short duration of the symptoms, lasting only a few days, or at most a couple of weeks.¹² The problem of feeble-mindedness¹³ is an extremely important one. In view of the fact that we do not have labor battalions in this war, every man has to be able to be a fighting soldier or there is no place for him.

Individuals with psychosomatic complaints constitute a large portion of the practice in the gastrointestinal, cardiac and orthopedic services. These soldiers because of the nature of their complaints, are referred directly to these services. From various sources, particularly combat areas there is evidence that the gastrointestinal disturbances are probably most frequent. The importance of the psychologic factors in the production of even the peptic ulcer is summarized by Thomas¹⁴ as follows: "When viewed in a broad way, the mass of experimental and clinical observations which have been published recently emphasize the large part that is played by psychic factors in the production and continuation of peptic ulcer. A study of cases of peptic ulcer in the Army lends further proof to this concept." The great majority of cases seen in our army hospital gastrointestinal wards have not progressed to the ulcer stage.¹⁵ All represent fundamentally a total personality disturbance and as such are primarily psychiatric problems. If regarded as such and so treated, many of these soldiers may be salvaged.

The so-called neurocirculatory asthenia,¹⁶ brought to light in the last war, continues to be a fairly frequent finding, although it is too often regarded as having an entirely organic basis. Every army orthopedist is confronted too frequently with a syndrome of low back pain in which he finds no anatomic or physiologic explanation. In many hospitals they are referred to the neuropsychiatric wards and unfortunately they are rarely salvageable for the Army. One of the most common problems in this group of psychosomatic disturbances is headache in which no organic or chemical pathologic condition can be determined. They often present very difficult diagnostic problems. All of these reactions call for the closest of team work between the internist and the psychiatrist. The enormous frequency of their occurrence in the Army affords an unusual opportunity for research in the age old somapsychic relationships.

intracranial block. Such an expression is usually not clearly after an apparently normal cord has been explored.

The problem occurs only when the level involved above the conus equinus or the conus medullaris. Many space-occupying lesions below the spinal cord do not change the dynamics of the spinal fluid. Most of them are the herniated intervertebral cartilage. The level of the second lumbar vertebra was chosen arbitrarily to represent the lower limit of the spinal cord, and no lesions at or below this level were included in the present study. Conditions such as multiple sclerosis, neurosyphilis, optic and virus infec-

a ruptured intervertebral cartilage or a tumor (table 1). In other words, 30 per cent of the patients in this series suspected of having a cord compressing lesion did have just such a pathologic condition, for which surgical measures are indicated, despite the absence of spinal block. Another 20 per cent (table 2) displayed a lesion in the nature of arachnoiditis or of pachymeningitis in which the separation of adhesions is known occasionally to result in mild improvement. The remaining 10 with exploration, or 50 per cent of the patients in this series (table 3), showed a normal appearance of the spinal cord atrophy of the cord or other noncompressing pathologic change. An occasional

tion of the spinal cord, which sometimes produce a level lesion but cannot be expected to improve through surgical means, are not being considered.

In the neurologic service at Bellevue Hospital (Cornell Division) in New York during a thirteen year period, 1930 to 1942 inclusive, 20 patients suspected to have a compressing lesion of the spinal cord above the second lumbar vertebra were operated on in the presence of a perfectly normal Queckenstedt sign. The suspicion of the presence of a space occupying lesion was not strong with regard to some of these patients, but, since there was a doubt, surgical procedures were undertaken.

Of the 20 patients with an "open" spinal fluid system, 10 showed some pathologic process intruding on the spinal cord for which surgical intervention bore hope of improvement. Of these 10, 6 had a definite space occupying localized compressing lesion, such as

patient of this type, often referred to as having "intrinsic cord disease" is known to display in some mysterious fashion, considerable improvement after laminectomy,

TABLE 4—*Protein Content of Spinal Fluid*

	Cases in Which Content Was Normal to 45 Mg. per 100 Cc.	Cases in Which Content Was Elevated		
		Slightly Elevated 55-65 Mg. per 100 Cc.	Moderately Elevated 70-95 Mg. per 100 Cc.	Grossly Elevated 100-220 Mg. per 100 Cc.

Arachnoiditis	2	1		

despite the failure to find gross pathologic abnormality. Relationship of such a remission to the surgical procedure is certainly not proved but has been suggested.

Sachs and Glaser⁵ reported occasional improvement after exploratory laminectomy on patients showing no pathologic changes ordinarily considered to be improved by the surgeon. They found that 8 of 33 patients of this type showed clinical recovery.

An attempt was made to correlate the operative findings with some of the more commonly emphasized physical and laboratory signs, namely the protein content of the spinal fluid, the presence or the absence of sacral anesthesia, and the sharpness of definition of the sensory level.

With regard to the values for protein, our study revealed that of the 6 cord compressing lesions 4 had produced a very high protein content in the spinal fluid and that 2, an extradural neoplasm and a herniated disk, were accompanied by normal protein values. As to the 4 cases showing meningeal adhesions, the protein content was within normal limits in 2, slightly elevated in 1 and definitely increased in 1. Of the 10 patients with an apparently normal cord or with intrinsic or other nonoperable disease of the cord 2 had moderately elevated and 3 slightly elevated protein values, and the

TABLE 5—Sacral Anesthesia

Arachnoiditis	1	3

remainder had values within normal limits. Although realizing the limitations of so small a series, we noted (table 4) that only the operable lesions in this group produced the very high protein levels.

With regard to the other correlations attempted, no such clearly defined trends are apparent. Sacral "saddle" anesthesia (table 5) was present with sufficient frequency in every one of the categories to be of little significance in the differential diagnosis. Again the cases were too few to support any definite conclusions. Similarly with the preciseness of the sensory level (table 6) each group had an equal distribution of patients with concise and patients with uncertain levels.

CONCLUSION

It is felt that this summation indicates the advisability of surgical exploration in a patient suspected of having a level lesion of the spinal cord despite the absence of spinal fluid block.

It is also seen that a high protein content of the spinal fluid (above 100 mg per hundred cubic centimeters) in such a patient is strongly suggestive of a localized compressing lesion, whereas the presence or the absence of sacral "saddle" anesthesia and the preciseness or the vagueness of the sensory level may not be of great significance in the diagnosis.

2-ANILINOETHANOL—AN INDUSTRIAL HAZARD

PRODUCTION OF METHHEMOGLOBINEMIA

ALLAN D. BASS, MD

L. H. IROST, MD

AND

WILLIAM T. SAITLER, MD

NEW HAVEN, CONN.

That aniline derivatives produce methemoglobinemia has been shown repeatedly by many investigators. The mechanism of this reaction has been reviewed by Bernheim.¹ One molecule of aniline combines with two of hemoglobin to give two molecules of methemoglobin and one of p-hydroxyaniline. To our knowledge it has not been shown that 2-anilinoethanol causes formation of methemoglobin but from analogy this might be expected to occur in the course of its metabolism in the body. That such is the case was suspected when 2 men in a commercial plant developed cyanosis while using this compound under the name "phenyl ethanolamine." No immediate means of testing the blood for methemoglobin was available in the local hospital, so that the etiologic agent of the cyanosis could not be definitely established. Both men rapidly recovered.

REPORT OF CASES

CASE 1—S. R., a Lithuanian aged 52, began work at 7 a. m. on Nov. 27, 1942 washing bearings with "mineral seal oil" containing 0.5 per cent "phenyl ethanolamine." He had been working for six years at the same task using the mineral seal oil, but on this day a sample admixed with 2-anilinoethanol was employed for the first time. At 2 p. m. a fellow worker noted that there was a bluish discoloration of the patient's lips and of the lobes of his ears. He continued at work until 4 p. m., at which time he had a mild occipital headache and a "feeling" that he was "taking a cold." He took two compound cathartic pills and continued at work until 5:30 p. m., at which time he quit work and went to see a physician. Although not acutely ill, he was sent to a hospital because of the cyanosis. He was put to bed and oxygen administered. The cyanosis progressed until about 11 p. m., then gradually subsided and had entirely disappeared twenty-four hours after admission.

Physical examination gave essentially negative results except for the profound cyanosis involving both skin and mucous membranes. The blood was a deep brownish blue, and the urine was dark. Routine studies revealed no abnormalities of the urine or the blood. Recovery was rapid and complete.

CASE 2—M. C. Q., a white married man aged 53, began working at 12 noon on Nov. 27, 1942 with the same solution as described in the preceding case. At 6 p. m. a fellow worker noted that the patient's lips, nose and ears were blue. The patient was asymptomatic except for slight dizziness and mild pains in the muscles of his legs. When he reported to the first aid nurse at 8:45 p. m. it was necessary for him to sit upright to breathe. He arrived at the hospital at 10 p. m. at which time oxygen was administered. His cyanosis progressed until 1 a. m. and then receded steadily until it was entirely gone twenty-four hours after he entered the hospital. Physical examination revealed no abnormalities other than cyanosis and dyspnea. The urine was normal. The blood was dark brownish blue but otherwise showed no abnormalities.

From the Laboratories of Pharmacology and Toxicology, Yale University School of Medicine.

Dr. Albert S. Gray and Dr. Crit. Pharris of the Connecticut State Department of Health Bureau of Industrial Hygiene assisted in obtaining the chemicals studied. Technical assistance was given by Miss Ruth Jaffe and Mr. Vincent Tucker. The manufacturer cooperated by supplying immediately samples of the commercial material and by preparing specially purified material for further study.

¹ Bernheim, Frederick. "The Interaction of Drugs and Cell Catalysts." Minneapolis: Burgess Publishing Company, 1942.

PRODUCTION OF THE INDUSTRIAL ACCIDENT INVOLVED

The manufacturing operation in which the 2 men were covered was the washing of a sanded roller by holding them in a stream of mineral seal oil containing 0.5 per cent by volume of 2-aminioethanol, called phenyl ethanolamine. The solution was being

sprayed through nozzles at a pressure of 80 pounds per square inch. The washing bath was so constructed that the spray stream was directed away from the operator and against the back wall and down into the distribution system. There was good ventilation of the bath to remove spray mists, in fact it was impossible to see any mist around the booth while it was being used. This cleaning operation had been carried out for a number of years with mineral seal oil as the basic ingredient of the spray. No trouble had been experienced until 2-aminioethanol was added. The casualties occurred on the first day that the cleaning mixture was altered. The relative importance of cutaneous and pulmonary points of entry requires further study.

TOXICOLOGIC INVESTIGATION

Two samples of 2-aminioethanol were supplied to us for toxicologic study: one a technical grade of 2-aminioethanol, the same that was used by the industrial workers, and the other a pure sample kindly prepared by the manufacturer.

Normal adult dogs fed on commercial chow were subjected to 2-aminioethanol by various routes. Methemoglobin was determined by the method of Evelyn and Malloy² with a Klett-Summerson photoelectric colorimeter. Acute toxicity experiments were carried out on 15 dogs, 8 rabbits and 95 mice, in addition to chronic toxicity experiments on 11 dogs.

Pathologic studies, both gross and microscopic, were made on those subjected to chronic poisoning.

2 Evelyn, K. A. and Malloy, H. T. Microdetermination of Oxyhemoglobin, Methemoglobin and Sulfhemoglobin in a Single Sample of Blood. *J. Biol. Chem.* 126: 665 (Sept.) 1938.

Studies of Toxicity—The 2-aminioethanol was dissolved in a dilute solution of ethyl alcohol for injection into mice. The undiluted drug was used in dogs and rabbits. The rate of intravenous administration was slow because rapid injection was known to cause respiratory arrest and immediate death. Emesis uniformly followed the administration of the larger doses to dogs within the first ten minutes. No signs of immediate toxicity were noted in rabbits and mice except for transitory stupor and ataxia during the first three to ten minutes. Usually if death was not immediate it was delayed for six to twelve hours.

(a) **Effect on Blood Cells**—Studies were made of the blood of 4 dogs after administration of 2-aminioethanol. Two dogs treated repeatedly at one to two day intervals with 110 mg per kilogram injected subcutaneously showed no change of the granulocytes or mononuclear white cells either in numbers or in structure. In one of these animals the hemoglobin dropped from 14 Gm to 9 Gm per hundred cubic centimeters of blood in twenty-one days and in the other animal from 12 Gm to 6.5 Gm per hundred cubic centimeters in a ten day period. By the twenty-seventh day the hemoglobin of the first dog had returned to 10.5 Gm and that of the second to 11 Gm per hundred cubic centimeters on the twenty-fourth day.

In a dog given 220 mg per kilogram subcutaneously at frequent intervals (one to two days) severe anemia developed (7.5 Gm hemoglobin per hundred cubic centimeters of blood) by the seventeenth day. The fourth animal, which died four days after treatment, showed a fall in hemoglobin from 11 to 8 Gm per hundred cubic centimeters and of the erythrocyte count from 4.8 to 2.5 million per cubic millimeter shortly before death. The red cell count fell uniformly in all 4 dogs but only the last of these animals showed a drop corresponding to the low hemoglobin. There was a slight increase in the number of nucleated red cells and in the polychromatophil red cells. No increase in reticulocytes could be demonstrated on the fifteenth day.

(b) **Production of Methemoglobin**—Four curves are shown in the accompanying chart to illustrate the concentration of methemoglobin in the blood at various times following the oral or the intravenous administration of the crude 2-aminioethanol to dogs. By either route of administration the peak of methemoglobin was reached in from two to four hours. The rise, however, was delayed somewhat when the oral route was used.

In 2 other animals when 2 cc of drug was spread over an area of depilated skin 15 by 15 cm methemoglobin rose only to 6 and 12 per cent respectively.

A 31 Kg dog was allowed to breathe the atmosphere from a 500 cc beaker held over its mouth and nose. Into this beaker was sprayed 2 cc of 2-aminioethanol in 10 cc of ethyl ether. Cardiac blood samples revealed methemoglobin concentrations of 20.8 and 48 per cent at intervals of one hour fifteen minutes and four hours forty-five minutes respectively.

In the rabbits and the mice negligible amounts of methemoglobin were formed when 2-aminoethanol was injected intravenously. We are informed, however, by the manufacturer that recent observations indicate that rats are susceptible.

Blood from treated dogs when examined by a hand spectroscope showed spectral bands corresponding with those of methemoglobin prepared in vitro by adding potassium ferricyanide to normal blood.

The experiments described were conducted with the commercial product as marketed. Methemoglobin curves similar to those shown in the chart, however, were obtained when purified 2-aminoethanol was employed. It is evident therefore, that this compound is the agent producing the methemoglobinemia, and not a contaminant present in the crude material.

Chemical Tests—Alles² has discussed the formulas of two phenylethanolamines, i. e., α -phenyl, β -aminoethanol ($C_6H_5CHOHCH_2NH_2$) and β -phenyl, β -aminoethanol ($CH_2OHCH(C_6H_5)NH_2$). Either of these compounds is a primary amine and should react with nitrous acid to yield elementary gaseous nitrogen. When this test was applied to the substance under discussion, however, no gas was evolved. Furthermore, a reddish oil was formed, insoluble in water at pH 2.5 under conditions which readily dissolved the original so-called phenyl ethanolamine. In short, this substance did not behave like a primary amine. Furthermore, on boiling with chloroform and potassium hydroxide the compound gave no disagreeable isonitrile odor. The most likely interpretation therefore, is that the substance is a secondary amine, i. e., 2-aminoethanol ($C_6H_5NHCH_2CH_2OH$). It is a colorless liquid with a density of 1.114 g./cm. per cubic centimeter, boiling at 286°C. It is only slightly soluble in water but is soluble in alcohol. A comparison of the properties of the substance under discussion showed good agreement with the anticipated findings.

COMMENT

It is hoped that the reporting of these cases will call the attention of physicians in industrial practice to the necessity of critically investigating the structure and properties of new compounds. The name phenyl ethanolamine would naturally identify the compound in question as an epinephrine-like substance³ and therefore is quite misleading. If the compound had been named however, as an aniline derivative or if the chemical formula had been placed on the label, an error of this nature should not have occurred.

On discussing the problem with Dr. G. A. Alles, he kindly consented to our quoting the following:

It is unfortunate that the term phenyl ethanolamine has come to be applied commercially to ethanolamine or 2-aminoethanol. The term ethanolamine is far more suitable to indicate the special chemical properties of the compound among types of amino alcohols now manufactured and used industrially. From the standpoint of its toxicology also the name ethanolamine would readily bring to the minds of those with elementary pharmacological knowledge its potential toxicities in industrial use. Certainly if the nomenclature of phenyl ethanolamine be persisted in the compound should always be designated as N -phenyl ethanolamine to distinguish this compound from the earlier described and used α - and β -phenyl ethanolamines.

This problem of nomenclature arises from the long established custom of giving greater importance to oxygen than nitrogen in the systematic naming of organic compounds. This

emphasis is particularly unfortunate in the group under consideration because the amino character of these compounds so completely dominates their properties for industrial use and determines their characteristic physiological activities.

CONCLUSIONS

An oil mixture containing 2-aminoethanol (improperly named "phenyl ethanolamine") caused cyanosis in 2 factory employees using it. This substance likewise produced cyanosis in dogs but not in rabbits and mice. As established in dogs, the presence of methemoglobinemia is the cause of the cyanosis.

Because this problem of toxicity is likely to arise repeatedly as new industrial uses are found for the many related chemical substances which will be available this example has been cited.

The hazard of such intoxication of human beings might be mitigated if special care was taken that similar substances are named as aniline derivatives. At least a cautionary label should be applied to warn industrial safety committees of the danger.

FAILURE OF SULFACUANIDINE THERAPY IN THE CONTROL OF AN INSTITUTIONAL TYPHOID CARRIER

TRAVIS P. BURROUGHS, M.D.
Acting Director, Division of Communicable Disease Control, Delaware
State Board of Health and Surgeon (R) U. S.
Public Health Service
DOVER, DEL.

AND

F. A. FREYHAN, M.D.
Assistant Physician, Delaware State Hospital
FARMHURST, DEL.

REASON FOR ATTEMPTING CHEMOTHERAPEUTIC CONTROL

In spite of routine typhoid inoculation of all patients and personnel 4 cases of typhoid occurred in the Delaware State Hospital during the period 1934-1942. This is a hospital for nervous and mental diseases its annual average census ranging from 1,180 to 1,200 patients. The entire population of the hospital had been immunized against typhoid in 1933, when 4 cases occurred in Ward B East, routine admission immunization being instituted at the same time. All immunizations were the usual three subcutaneous injections of a standard triple typhoid vaccine.

In 1933 typhoid developed in a graduate nurse on duty in Ward B East. In 1937 a male patient contracted the disease. He did not live in Ward B East, which is a women's ward, but did help in the hospital laundry serving that ward. In 1938 a female attendant in Ward B East came down with typhoid and on Oct. 2, 1942 a woman patient was found to have the disease. She had been admitted to the hospital in March 1941 at which time she received the usual admission immunization against typhoid. She had been a patient in Ward B East since April 1942. Being feeble-minded in a state of advanced mental deterioration extremely confused and untidy she never left the ward for social activities. For six months prior to the onset of her typhoid she had no visitors and had not been exposed to any outside contacts whatever. She died on October 7, autopsy revealing Pick's disease as well as typhoid.

It seemed probable that the source of infection of this patient would be found in the ward itself. A systematic search for a carrier was therefore instituted by one of us (T. P. B.) beginning with those persons both patients and staff who were known to have had some connection with the ward at each of the various times when typhoid infection occurred. Eberthella

Alls, G. A. Comparative Action of Phenyl Ethanolamine J. Pharmacol. Exper. Therap. 12, 1 (June) 1937.
3 Described as compound 3509 in the Handbook of Chemistry and Physics, 2d ed., Chemical Rubber Publishing Company, 1941-1942.

feces reported from successive specimens of feces a week apart started by I. A. patient, while specimens of feces of I. A. from the remaining 71 patient and staff in the ward were all negative. I. A. white woman aged 71, school principal, was the 2 surviving patient who had typhoid in 1933. Her carrier condition at that time was not stated. During the ten years preceding this she had been confined continuously to Walter P. Hospital, a private sanatorium of the ward. However, I. A. had been treated elsewhere. It was very difficult to trace her previous stay away from other patients. The carrier condition was not fully confirmed by the fecal examination. As for the fecal examination, the results were essentially confirmed. It was not possible to give them as a carrier. The carriers were not infected or infection impracticable. It seemed wise to try sulfaguanidine therapy.

Specimens of feces are reported to have no favorable results of typhoid and their use is ordinarily not reported. In some instances favorable results have been reported in the treatment of typhoid carriers and in blood stream infections with gram-negative intestinal organisms while Horgland¹ reports successful treatment of 2 out of 3 typhoid carriers with sulfaguanidine. Accordingly it was decided by one of us (I. A. I.) to institute sulfaguanidine therapy.

For some years the carrier had shown a rather constant although mild albuminuria and granular casts had been found on numerous occasions. Urine of specific gravity ranging from 1.013 to 1.024 was obtained on a dilution test and a specific gravity of 1.030 on concentration test. On a phenolsulfonphthalein test 12 per cent of the dye was recovered at 70 minutes after injection and 35 per cent 130 minutes after injection. In view of the fact that the carrier had had some kidney impairment it seemed wise to start with a small initial dose. Treatment was begun on Dec 21, 1942 with 6 Gm a day of sulfaguanidine by mouth. The dosage was increased to 12 Gm a day on the twelfth day, January 1, and to 18 Gm a day on the fifteenth day, January 5, this last dose being nearly the maximum of 20 Gm a day advocated by Horgland in cases in which smaller doses are ineffectual. There had been increasing loss of appetite during the administration of sulfaguanidine, and the patient had seemed to grow more apathetic but had not been seriously incapacitated. When the dose was increased to 18 Gm a day, she became weak, mildly cyanotic, began to vomit and refused all food. On January 7 and 8 she was given 1,000 cc a day of saline solution with 5 per cent dextrose solution intravenously. Because of her schizophrenic mental state nothing could be learned as to subjective symptoms, but general malaise was obviously present to a pronounced degree. The temperature, which had been normal throughout the treatment period, rose on January 7 to 99 F and on January 8 to 102 F. Treatment with sulfaguanidine was discontinued on January 8. Two days afterward the temperature fell to a normal level. Complete blood counts during the course of treatment were all within normal limits. Treatment was maintained at the 18 Gm level for a total of four days. The carrier thus received a total of 174 Gm of sulfaguanidine. Her carrier condition at no time showed even the slightest effect from treatment. Specimens of feces were found positive on Dec 12 and 28, 1942, Jan 9 and 12 and April 20, 1943. Within a few days after sulfaguanidine treatment was discontinued the patient recovered her usual health. No delayed reaction to the drug had appeared by June 29, 1943.

SUMMARY

A chronic typhoid carrier discovered in a mental hospital continued to discharge typhoid organisms in her feces while receiving sulfaguanidine by mouth at the rate of 6 to 18 Gm a day. She was still a carrier after eighteen days of treatment in which she received a total of 174 Gm of sulfaguanidine.

SUCCESSFUL SURGICAL TREATMENT OF MULTIPLE ATRESIAS (APIASIAS) OF THE SMALL INTESTINE IN A PREMATURE INFANT

FELICE A. T. PETER, A. D. C. A. U. S.
E. STAFFORD WEAR, M.D. HERBERT F. JACOBSON, M.D. NEW YORK,
AND FELICE A. T. WILLIAM S. WALDRON, M. C. A. U. S.

Remarkable progress has been observed in the treatment of intestinal atresias during the past fifteen years. Prior to 1927 only 4 cases of atresia of the intestine had been successfully treated by surgery.¹ When Webb and Wangenstein² in 1931 reviewed some 500 reported cases of intestinal atresia, only 9 survivals could be found. Ten years later Cohen³ estimated that another 150 cases had been reported but that there were now over 50 instances of successful surgical treatment. It is difficult to estimate the operative survival following early and adequate surgical treatment as most cases have been reported individually or, at best, in small groups, owing to the comparative rarity of this condition. Ladd⁴ however, has recently published the results of 49 cases of atresia of the small intestine treated in his clinic. In this group there were 7 survivals (14 per cent).

Multiple intestinal atresias are infrequent in their occurrence. Davis and Poynter⁵ found 67 instances of multiple lesions in 392 cases of intestinal atresia collected from the literature, an incidence of 15 per cent. In Ladd's⁴ series there were 3 cases, or 5 per cent of the total group. Glover⁶ in 1942 estimated there had been fewer than 100 cases of multiple intestinal atresia reported. Very few of these cases have been treated surgically. To the best of our knowledge there have been no survivals. It is our purpose in this paper to report what we believe to be the first successful surgical treatment of a case of multiple atresias of the small intestine.

REPORT OF CASE

M. G., a white boy aged 36 hours, admitted to the Pediatric Service on Aug 28, 1942, had been born at a Bayonne (N. J.) hospital and referred to us with a diagnosis of congenital intestinal obstruction.

The pregnancy had been entirely normal until labor started one month prematurely. The latter was of short duration and followed by an uneventful delivery. Breathing started spontaneously and there was no evidence of birth injury. The weight at birth was 4 pounds 8 ounces (2,041 Gm). He had vomited everything fed by mouth up to the time of admission. Absence of stools since birth had been noted.

The infant was well developed and nourished, considering his prematurity. The skin was decidedly jaundiced but possessed good turgor. The scleras were icteric. The abdomen was soft and without palpable masses. Borborygmi were not audible and peristaltic waves were not seen. The remainder of the physical examination was essentially negative. The

infant weighed 4 pounds 4 ounces (1,928 Gm) and measured 18 inches (46 cm) in length

Nonprojectile vomiting occurred shortly after the infant was fed some dextrose solution. The vomitus was bile stained and without fecal odor. Fluoroscopic and roentgenographic examination revealed moderate gaseous distention of the stomach and duodenum, which ended abruptly in the region of the duodenojejunal flexure (fig 1). The remainder of the alimentary tract was entirely devoid of gas. Barium was not used in these studies. Liberal amounts of parenteral fluids were administered during the next twenty four hours. Vitamin K was injected intramuscularly. The stomach was lavaged clear immediately preceding the operative procedure.

The operation was performed by one of us (T S W) on August 29. With the patient under open drop ether anesthesia, a 6 cm upper right rectus incision was made. A dilated loop of small intestine bulged into the wound after the peritoneal cavity was opened. Further examination revealed the stomach, duodenum and proximal jejunum to be dilated with some thickening of the intestinal wall in these regions (fig 2). Approximately 10 cm below the ligament of Treitz the jejunum ended blindly. The next portion of bowel was an isolated loop approximately 4 cm in length. This was followed by a section of bowel 17 cm in length which also ended blindly at either end. Just proximal to its distal end there was a bulging caused by inspissated meconium (fig 3). On the antimesenteric side of the intestine in this area there was pronounced thinning of its musculature, and a small point of perforation was visualized. Both these blind loops of intestine were supported by individual mesenteries. They were completely separated from each other and from the other portions of the bowel. At the proximal end of the remaining loops of small intestine there were two areas of stenosis. Distal to these stenotic areas no further evidence of

Fig. 1—Thin flat film of the abdomen. Infant was held in an upside down position. The two smaller shadows on the left side of the abdomen are due to air present in the stomach. The larger curved shadow in the center of the abdomen represents air in the small intestine. The smaller end of this shadow is just above the point of obstruction. Note the absence of air in the remainder of the film.

atresia or stenosis was found in the small or large bowel. The intestine in these regions was completely collapsed but appeared to be patent.

The small uncomplicated isolated loop of jejunum was left undisturbed. The 17 cm loop of jejunum containing the perforation was resected (fig 3). Liquid petrolatum was then injected into the lumen of the uninvolved distal small intestine and seen to pass readily through the remaining portions of the small bowel. This was done to dilate the distal intestine preparatory to making the anastomosis. While this procedure was being carried out the mesentery of the proximal portion of the distal small intestine was torn loose for a distance of 3 cm. This necessitated resection of this portion of the small intestine which procedure was carried out just below the stenotic areas. The distal stump was cauterized with the actual cautery, inverted and closed with a number 00 chromic catgut suture passed on an atraumatic needle. Bleeding vessels in the mesentery were tied with number 00000 chromic catgut

sutures. This end of the small bowel was then sutured side to side with the upper dilated jejunum by continuous sutures of number 00 chromic catgut passed on atraumatic needles. The upper and lower loops were then opened. The anastomosis was made by a continuous stitch through the entire intestinal wall posteriorly. The suture was locked at either angle and

Fig. 2—Diagrammatic sketch of the abdominal findings at the time of operation.

brought anteriorly as a Connell stitch. A number 00 chromic catgut suture on an atraumatic needle was used for this procedure. The anastomosis was reinforced anteriorly with a number 00000 chromic catgut suture. The peritoneum was closed with a continuous suture of number 000 chromic catgut.

Fig. 3—The 17 centimeter isolated loop of jejunum which was resected because of perforation. Arrow indicates point of perforation.

Closure of the anterior rectus sheath was carried out in a similar manner. Retention sutures of number 1 silk were placed through the anterior rectus sheath. A continuous number 0 silk suture was used for the skin closure. The retention sutures were then tied. The duration of the operative

procedure was two hour. The patient was returned to the room in good condition.

The infant was placed immediately in a heated bed. Nothing was given by mouth during the first three postoperative days. Parenteral fluids were administered in liberal amounts. Small amounts of plasma or whole blood were given almost daily. Vitamin C and K were injected intramuscularly. The stomach was treated at regular intervals. The patient's general

Fig. 4—Anastomosis of the small intestine.

condition was good. The temperature of the skin was good and there was no evidence of infection. Slight respiratory distress was noted but there was no tracheal vomiting. The heart was not palpable.

At the end of the third postoperative day small amounts of sterile distilled water solution were given by gavage. A small amount of brown mucoid material was passed by rectum approximately twenty hours after the operation. Two days later a small amount of yellowish green mucoid material was passed, possibly indicating patency of the anastomosis. The infant weighed 4 pounds 7 ounces (2,013 Gm) at this time.

On the fifth postoperative day the infant was started on five volumes of sterile water every three hours followed the next hour by a formula composed of breast milk and barley water. The amount of the formula given was increased every four feedings. Two days later the infant developed a moderate generalized edema. The skin and retention sutures had cut through and were loose. The edges of the wound had separated but the interior rectus sheath remained firm. The wound was closed by means of an adhesive dressing. The infant's weight was 4 pounds 13 ounces (2,183 Gm). The amounts of the parenteral fluids were reduced until the edema had disappeared. Bottle feedings were started and readily taken on the eighth postoperative day. The stools had increased to six to seven a day had become watery and contained mucus as compared to the yellow pasty breast milk stools which were present during the first few days of these feedings. The diarrhea continued even after the breast milk had been lactified. Parenteral fluids were increased again on the twelfth postoperative day when evidence of dehydration reappeared.

A protein milk formula was started on the thirteenth postoperative day. During the first five days of this feeding the infant lost 7 ounces (198 Gm) in weight. It was observed at this time that the white blood cell count had increased up to 37,000 from its former range of 14,000-17,000. The stools had decreased in number and were of firmer consistency but chalky white. Urine specimens gave positive tests for bile. The jaundice, which had practically disappeared, increased in intensity. The infant appeared much weaker and required continuous external heat to maintain a normal body temperature. His breathing became rapid and shallow, and he was occasionally cyanotic. At one time he showed a definite carpopedal spasm. Sulfadiazine was started with the idea that this setback might have been of a septic nature. The white blood cell count fell promptly to its former levels following the administration of this drug. Calcium gluconate was injected intramuscularly and a preparation of crystalline vitamin D was added to the formula. Bile salts and vitamin K were administered because of the biliary obstruction. Most of the feedings had to be given by gavage during this period.

By the end of the third postoperative week the infant had made considerable improvement (fig. 4). Whole powdered milk was gradually substituted in the formula for corresponding

amounts of the protein milk. The infant became stronger and was able to take feedings by bottle once more. The stools were better digested and numbered from three to five a day. They appeared to contain bile but a positive laboratory test for this substance could not be obtained. The jaundice had decreased somewhat in intensity but bile was still detectable in the urine. The bile salts, calcium gluconate, sulfadiazine and vitamin K were discontinued. There was a steady gain in weight to 5 pounds 6 ounces (2,438 Gm) on the fortieth postoperative day.

During the next one and a half weeks there was an increase in the number of stools to six to seven a day. They became loose and were fatty in consistency. Parenteral fluids were given intensively but failed to stop a weight loss to 4 pounds 15 ounces (2,240 Gm). A protein milk formula was again instituted. This along with the administration of bile salts, brought about control of the diarrhea.

From this point the patient progressed very satisfactorily. Whole powdered milk eventually replaced protein milk completely in the formula. Lactose was gradually added to the formula and was tolerated well. Cereal was started one week before discharge from the hospital. Bile salts were discontinued after they had been given for a period of four weeks. Jaundice gradually decreased and had disappeared entirely by the end of the second postoperative month. The stools became small were normal in consistency and contained bile. However, they numbered four to five daily until the last two hospital weeks, when they decreased to two a day. The last positive test for bile in the urine occurred on the sixty-third postoperative day. There was a steady gain in weight up to 7 pounds 4 ounces (3,288 Gm) at the time of his discharge on

Fig. 5—Appearance of the patient at the age of 10 months.

the one hundred and ninth hospital day. He had developed a diastasis recti at the operative site, which was controlled by an abdominal binder. Otherwise the discharge examination was essentially normal.

The patient was seen again at the age of 6½ months. At this time he was in excellent health and weighed 15¼ pounds (6,917 Gm). He had had varicella during the preceding month. There had been no evidence of dietary intolerance. No signs or symptoms referable to the gastrointestinal tract had

been observed. The remainder of the physical examination was negative except for the diastasis recti. When seen on June 29, 1943 at the age of 10 months, the patient appeared in excellent health (figure 5). He had recently undergone an attack of rubella without difficulty. Examination was again negative except for the weakness of the abdominal wall due to the diastasis recti. The feeding and developmental history was within normal limits. He now weighed 18 pounds (8.2 Kg) and measured 30 1/2 inches (76 cm) in length.

COMMENT

Since several reviews on intestinal atresia had appeared in the recent literature," discussion will be limited to those factors believed important in the successful outcome of the present case.

The first essential in increasing the number of successfully treated cases of intestinal atresia rests in its early recognition clinically. While some of these infants have lived as long as three weeks without surgical treatment the average age at death is 6 days.⁶ Therefore the obstetrician who is most likely to come in contact with these cases first should be well acquainted with its early clinical manifestations. Persistent vomiting of all feedings from birth along with the absence of stools should always suggest the possibility of intestinal atresia. Other clinical findings vary with the location of the lesion and these are well discussed in the aforementioned reviews. The early recognition of congenital intestinal obstruction in the present case permitted us to operate while the infant was still in an excellent state of hydration and nutrition.

Röntgenology is of great aid in the diagnosis and localization of intestinal atresia. Adequate information may be obtained from a plain flat film of the abdomen.⁸ Sufficient contrast material is provided by the large amounts of air swallowed by newborn infants. In the presence of intestinal atresia the swallowed air is unable to progress beyond the point of the obstruction. The dilated outline of the portion of the intestine above the atresia and the absence of gas in the distal bowel are usually clearly demarcated. The use of a barium contrast meal in most instances is unnecessary. It has been stressed that such studies may be detrimental.⁹ Barium can easily plug and obstruct the undilated portion of intestine beyond the atresia once the anastomosis has been made. Another objection is that the inclusion of barium within the anastomosis would delay or even prevent its healing. This point needs emphasis as cases in which barium studies have been done continue to appear in the literature and in our own personal experience.

The need for adequate maintenance of fluids and electrolytes in infant surgery has become well recognized in recent years. It has been rightly emphasized that operation should be delayed in the presence of dehydration until restoration of tissue fluids and electrolytes has been accomplished.¹⁰ The recognition of this fact has materially influenced the operative successes in the newborn period. That infants in a state of good nutrition and hydration can withstand major surgical procedures of long duration is amply demonstrated in the present case. The administration of parenteral fluids postoperatively in the treatment of cases of atresia is especially important. Oral feedings are not given in the immediate postoperative period in order to permit healing of the anastomosis without enteric irritation. Thus the entire maintenance of tissue fluids and electrolytes is dependent on their parenteral administration.

Recent investigations¹¹ have revealed an elevated prothrombin clotting time in the newborn period particularly in premature infants even when clinical evidence of hemorrhagic disease is

lacking. Many studies have revealed the efficacy of vitamin K in the therapy of this bleeding tendency.¹² Patients undergoing any operative procedure in the neonatal period should receive adequate parenteral administration of vitamin K operatively and for a short period in the postoperative course as a routine procedure.

There are recorded instances in which an anastomosis has been performed for what at operation appeared to be a single stricture to find at necropsy that multiple stricture lesions had been present.⁶ At the time of the operation therefore it is essential to explore the entire intestinal tract completely. In some cases the extent of the abnormalities will preclude any operative attempt. However the successful treatment of multiple lesions, illustrated in the present case will be possible in certain instances.

There is general agreement at the present time that the operation of choice is a side to side anastomosis.⁴ The small distal intestine precludes the use of an end to end anastomotic procedure. Except for a few cases, enterostomy has been invariably fatal. I add has stressed a minimal amount of surgery at the time of the primary operation. He advises leaving uncomplicated isolated loops intact. Their removal at a later date is recommended because of possible cyst formation. The presence of gangrenous or perforated intestine necessitates resection of the involved bowel. These principles were followed in the present case. The small uncomplicated blind loop of jejunum was left undisturbed while the larger isolated loop containing the perforation was resected. At the time of the present writing there has been no evidence of cyst formation in the blind loop still remaining in the abdomen.

Definite evidence of biliary obstruction appeared in our case during the third postoperative week. This persisted and did not completely clear until the end of the second postoperative month. Stetten¹⁴ reported biliary obstruction occurring earlier and of shorter duration following a duodenojejunostomy for an atresia at the duodenojejunal junction. In his case there was also protracted vomiting postoperatively. There was temptation for further surgery in both these cases. That they were functional disturbances was proved by the subsequent clinical course in both instances. We therefore believe that secondary operations for apparent operative complications in the early postoperative period should be entered on with considerable hesitancy.

A severe diarrhea developed in our infant several days after starting a breast milk formula. Stetten¹¹ had a similar experience in his case. The diarrhea was promptly brought under control when a protein milk formula was instituted in both of these cases. This would seem to indicate that protein milk is preferable to breast milk as the postoperative feeding.

Our infant received twenty-five transfusions of either whole blood or plasma by vein during the first four postoperative weeks. These provided adequate nutrition during a period when the oral intake was insufficient. There is no question that these repeated transfusions played a large role in the successful outcome of the present complicated case.

SUMMARY

Multiple atresias (aplasias) of the small intestine of a premature infant were given surgical treatment successfully. A small isolated loop of jejunum was left undisturbed. A larger blind loop of jejunum was resected. This loop contained a perforation caused by inspissated meconium. The proximal end of the distal small intestine containing two areas of stenosis, was resected because its mesentery was torn during the operative procedure. A side to side anastomosis was made between the distal intestinal stump and the proximal dilated jejunum. A prolonged period of biliary obstruction and two episodes of severe diarrhea complicated the postoperative course.

The radiation output of the Westinghouse bactericidal tube at various wave bands is shown by the accompanying table of energy distribution

The electrical input power required to operate the C-I unit is approximately 50 watts

When a unit is installed, the purchaser should make sure that a sufficient number of lamps are used to produce the correct amount of intensity in the enclosure and that they are arranged correctly so as not to cause harm to the occupants. The Council cannot undertake the supervision or assume the responsibility for satisfactory performance of any particular installation.

The Council on Physical Therapy voted to include the Westinghouse C-I Bactericidal Lamp in its list of accepted devices

WESTINGHOUSE CONSTANT INTENSITY STERILAMP UNITS

(Operating Room, Hospital Nursery and
Hospital Ward Models)

WITHDRAWAL OF ACCEPTANCE

Manufacturer Westinghouse Electric and Manufacturing Company, Radio and X-Ray Division, Baltimore

The Westinghouse Constant Intensity Sterilamp Units, Operating Room, Hospital Nursery and Hospital Ward Models, were announced as acceptable to the Council in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION of May 2 1942. The units were declared to be a useful supplementary measure of asepsis in hospital nurseries, wards and operating rooms where conditions are carefully controlled.

At the time the Constant Intensity Sterilamp units were submitted by the Radio and X-Ray Division of the Westinghouse Electric and Manufacturing Company for consideration by the Council, it was asserted that the complete term "Constant Intensity Sterilamp Units" would be used only for the hospital units, and that this distinction would serve to differentiate between the devices used for accepted purposes and the Sterilamps publicized for other purposes. This has been found to be an impractical arrangement and has proved to be misleading to the profession and to the public.

The term 'Sterilamp' has been widely publicized by the Westinghouse Electric and Manufacturing Company. Through extensive publicity it has been presented to the public as a designation for an apparatus that will kill bacteria in lavatories, bakeries, breweries, wineries, canneries, restaurants and so on. It is also claimed to aid in the tenderizing of meat. Such uses are stated in paid advertisements for the Westinghouse Electric and Manufacturing Company. Moreover, publicity for the name 'Sterilamp' and for the apparatus is also solicited by the firm in another manner: an active 'news service' for the company distributes among various lay and professional publications news stories concerning the device. These stories are prepared in such a manner that they may be inserted in the regular columns of the magazine; photographs also are furnished. The items are naturally of a somewhat sensational nature and many of them appear to be finding a place in widely read publications.

An advertisement in *Science* for Oct. 16, 1942 shows a hospital operating room scene (the operating team without adequate protection) and carries the headline 'Abandon hope all Germs who enter here'. In the body of the advertisement after a description of the unit it reads: 'The commercial applications of the Sterilamp are practically endless. It is used in the Tenderay process for tenderizing meat and in bakeries, breweries, wineries, canneries, restaurants, biological laboratories, lavatories, wherever air borne bacteria must be killed or controlled.' This advertisement definitely complicates the hospital and the commercial uses of the Sterilamp.

The similarity in the names of the accepted Constant Intensity Sterilamp Units accepted for hospital use and the Sterilamp employed for purposes which have not been submitted for acceptance to the Council and the overlapping publicity are considered misleading. The public has no means of discerning an application acceptable to the Council from one that has not been considered by it.

The Council voted to withdraw the acceptance of the Westinghouse Constant Intensity Sterilamp Units.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED IN CONFORMITY TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NON-OFFICIAL REMEDIES. A COPY OF THE RULES OF WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

MAY 1 1943 SECRETARY

EPHEDRINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1943, p. 255)

The following dosage form has been accepted:

BURROUGHS WILCOX & Co, Inc, New York

Solution Ephedrine Hydrochloride, 3 per cent. Preserved with chlorobutanol 0.5 per cent, 1 fluidounce and 1 pint bottles.

LIVER INJECTION (See New and Nonofficial Remedies, 1943, p. 392)

The following dosage forms have been accepted:

THE UPJOHN COMPANY, KALAMAZOO, MICH.

Liver Extract for Parenteral Use, 5 U S P Units per Cc. 2 cc ampul and 10 cc rubber capped vial. A sterile aqueous solution of liver preserved with 0.5 per cent phenol.

Liver Extract for Parenteral Use, 10 U S P Units per Cc. 1 cc and 1½ cc ampuls and 10 cc rubber capped vial. A sterile aqueous solution of liver preserved with 0.5 per cent phenol.

PROCAINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1943, p. 82)

The following dosage form has been accepted:

THE UPJOHN COMPANY, KALAMAZOO, MICH.

Sterile Solution Procaine Hydrochloride 2%, 30 cc rubber capped vials and 100 cc bottles. Each cubic centimeter contains chlorobutanol 50 mg, procaine hydrochloride 20 mg, sodium bisulfite 10 mg, sodium chloride 84 mg.

SULFANILAMIDE (See New and Nonofficial Remedies 1943, p. 175)

The following dosage forms have been accepted:

AMERICAN PHARMACEUTICAL Co, Inc, New York

Sulfanilamide (Powder) 1 ounce, 4 ounce and 1 pound packages

PITMAN-MOORE Co, INDIANAPOLIS

Tablets Sulfanilamide 0.324 Gm (5 grains)

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1943, p. 590)

The following additional dosage form has been accepted:

SCHIFFELIN & Co, NEW YORK

Tablets Thiamine Hydrochloride 10 mg

ARSPHENAMINE (See New and Nonofficial Remedies 1943, p. 198)

The following additional dosage forms have been accepted:

MERCK & Co, Inc, NEW YORK

Ampules Arspenamine 10 Gm and 30 Gm

NEOARSPHENAMINE (See New and Nonofficial Remedies 1943, p. 203)

The following additional dosage forms have been accepted:

MERCK & Co, Inc, NEW YORK

Ampules Neoarsphenamine 30 Gm and 45 Gm

PHENOBARBITAL (See New and Nonofficial Remedies 1943, p. 502)

The following dosage forms have been accepted:

AMERICAN PHARMACEUTICAL Co, Inc, NEW YORK

Tablets Phenobarbital 0.032 Gm, 0.016 Gm and 0.1 Gm

THE WARREN-TEED, PRODUCTS Co, COLUMBUS, OHIO

Tablets Phenobarbital 0.16 Gm, 0.08 Gm, 0.04 Gm

For the purpose of the American Medical Association, the following is a list of the names of the members of the American Medical Association who have been elected to the office of President of the American Medical Association for the year 1943-1944.

SATURDAY NOVEMBER 20 1943

SOUND MEDICAL PRINCIPLES FOR
MEDICAL PRACTICE

Nowhere in this issue appear the principles to govern the evolution of medical practice adopted by the Representative Committee of the British Medical Association and by representatives of many official bodies in Great Britain. This group comprised representatives of general practice, consultant and specialistic practice, public health, rural practice, medical staffs of provincial nonteaching hospitals and others. Special emphasis should be placed on the principle that the health of the people depends primarily on the social and environmental conditions under which they work, and that improvement and extension of measures to satisfy these needs should precede or accompany any future organization of medical service. Also fundamental is the principle that the efficiency of any medical service depends primarily on medical and scientific knowledge, which, in turn, is based on medical education.

The British group establishes the principle that the function of the state should be to coordinate existing provisions, both official and nonofficial, to augment these where necessary, and to secure that they are available without economic barriers. Supplementary to this is the statement that the state should confine itself within these wide limits, invading the personal freedom of both citizen and doctor only to the extent which the satisfaction of these functions demands. The platform of the American Medical Association likewise emphasizes the importance of an agency of the federal government, under which shall be coordinated and administered all medical and health functions of the federal government, exclusive of those of the Army and Navy, and the allotment of such funds as the Congress may make available to any state in actual need for the prevention of disease, the promotion of health and the care of the sick *on proof of such need*. The medical profession has not opposed appropriations by Congress of funds for medical purposes. It asks that the need be shown and that funds be locally rather than nationally administered.

The British Representative Committee again insists on free choice as between doctor and patient as fundamental to sound medical practice and states emphatically that it is not in the public interest that the state should invade the doctor-patient relationship. It is, no doubt, for this reason that the Representative Committee says that it is not in the public interest that the state should convert the medical profession into a salaried branch of central or local government service.

The Representative Committee of the British Medical Association advocates as a step forward in Great Britain the extension of the National Health Insurance Plan to include the dependents of insured persons and others of like economic status and to cover consultant and specialistic services and laboratory and hospital facilities, as well as general practitioner services. This statement indicates at once how completely lacking has been the National Health Insurance Plan in approximating anything resembling the quality of medical service that prevails in the United States. This recommendation again emphasizes that the National Health Insurance Plan of Great Britain covers wage earners up to a certain level of income only, that it has *not* included the dependents, that it has *not* included others than wage earners of low economic status, that it has *not* provided consultant and specialistic service, or hospital facilities or laboratory service. The gradual development of prepayment plans in the United States has recognized the need for such services. The medical profession has approved prepayment plans to cover the costs of hospitalization, and also prepayment plans on a cash indemnity basis for meeting the costs of medical care. Certainly the gradual evolution in the practice of medicine that has taken place in this country has led to higher standards of medical practice and of medical service than are elsewhere available. The maintenance of the quality of the service is fundamental in any health program.

The American Medical Association, through its House of Delegates, its Board of Trustees and its Council on Medical Service and Public Relations, has urged again and again the continuing evolution of medical practice, based on sound experimentation. Already many state and county medical societies, many industries and many insurance bodies have set up experiments of this type, some of which have already proved to be unsound. In this connection, therefore, the final recommendations of the Representative Committee of the British Medical Association, and of the Medical Planning Commission, deserve increased emphasis. They say:

There should be initiated, by arrangement and agreement between the government and the profession, organized experiments in the methods of practice, such as group practice, including health centers of different kinds, which should extend to general practitioner hospital units attached to general hospital. Future developments in group practice should depend on the results of such clinical and administrative experimentation.

Only by such controlled scientific experimentation can a sound system of medical service to meet the needs of all the persons in the community be developed

KETONES AS FUEL FOR MUSCLE CONTRACTION

Following the proposal of the now widely accepted theory of beta oxidation of fatty acids and the accumulation of supporting evidence, the view developed that there is an obligate coupling of oxidative reactions in the metabolism of fat and carbohydrate. The oft repeated aphorism that "Fats burn in the flame of the carbohydrates" was refined to the extent that 1 mole of dextrose was said to promote the oxidation of 2 moles of fatty acid without the production of ketone bodies. The latter compounds were tacitly considered products of the imperfect combustion of fat, without value to the organism and the removal of which was attended with more or less disturbance in the acid-base balance of the body and at times with actual tissue damage.

Further study of the metabolism of fat in the light of the implications of the theory of beta oxidation early indicated that other modes of oxidation of fatty acids are also operative in the organism. Now the position of ketone bodies has changed from that of a waste side-product of abnormal fat metabolism to that of a normal breakdown product of fats which in turn is utilized by the organism. Thus it has been shown that the muscle in a normal animal removes ketones from a perfusion fluid or from blood¹ and that this takes place also in the tissue of diabetic organisms.² In a recent report³ data both on human subjects and on experimental animals are cited to show again that ketones can serve as fuel for muscular activity. On ordinary balanced diets containing carbohydrate, vigorous exercise was accompanied by little if any decrease in blood ketone level. On a diet producing ketosis, however, a drop in concentration of ketones in the blood occurred during work with a rise following cessation of muscular activity.

The current view regarding the metabolic significance of ketones does not regard these compounds as accidental products of incomplete combustion of fats but rather as normal intermediates in fat metabolism constructively being produced by the liver⁴ and thence distributed to the tissues as fuel for work. When there is a lack of liver glycogen ketones become of major importance in the production of heat and mechanical energy by the muscles under these conditions the liver

apparently overproduces ketones, which accounts for the appearance of these compounds in the urine in ketosis. According to the newer views carbohydrate still influences the oxidation of fat, not however, in an obligate coupled reaction but because it is the preferred fuel for muscle action, the two are oxidized side by side, but in the absence of carbohydrate the emergency need for fuel is met by the accentuation of ketone production from fat. The locus of the influence of carbohydrate on fat metabolism appears to be essentially in the liver rather than in the tissues.

Current Comment

GUESSING AT PHYSICIANS' INCOMES

The U S Department of Commerce recently issued a release on the incomes of physicians of which the following sentence has been widely published and discussed: "The average gross income reported for 1941 was \$8,524, and the average net income \$5,047." Analysis of the methods by which these figures were obtained reveals that they are little more than guesses. The full report of the study on which they are based is printed in the "Survey of Current Business," issued by the Bureau of Foreign and Domestic Commerce of the U S Department of Commerce, October 1943, pages 16 to 20. From this we learn that "questionnaires were sent to a representative sample of physicians who were requested to give information relating to gross and net incomes, costs of practice, age, type of practice, employees, pay rolls and other selected items during the period from 1936 through 1941." A total of 1,898 returned questionnaires were used, about 1 per cent of the 180,496 physicians reported in the American Medical Directory for 1942, when the survey was made. One hundred of these questionnaires from the Southwest were excluded because of "a strong bias in the sample from Texas." For apparently the same reason the returns from Illinois, Indiana and Michigan were not included. There is no explanation of the method by which the sample was selected or any proof that it was representative. It is admitted that there were "special difficulties arising from the impracticability of obtaining a full representation of those of the younger doctors who were withdrawn from independent practice into the armed forces prior to the summer of 1942," but this is purported to have been allowed for by "weighting." In the summary table, returns from only twenty-one states are listed. Among those omitted, in addition to those previously mentioned, are Florida, North Carolina, South Carolina, Tennessee, Minnesota, Missouri and Wisconsin. On this very small foundation, nevertheless, is built an inverted pyramid of deductions, conclusions, diagrams and classifications based on income by age, localities, size of city and gradation of income, all given to the final dollar or to a decimal fraction, which gives a semblance of accuracy which the foundation of facts is entirely too slight to support.

SCHIRSON RESTORED LICENSE TO PRACTICE MEDICINE IN NEW JERSEY

The notorious career of Henry J. Schirson, self-styled plastic surgeon, has been repeatedly exposed in *The Journal*.¹ A medical abstract appearing in this issue (page 790) deals with the action of the Court of Errors and Appeals of New Jersey concerning this unscrupulous charlatan. The court has just reversed the order of the Board of Medical Examiners of that state which had previously revoked Schirson's license to practice medicine. Schirson at the time of revocation of his license to practice by the Board of Medical Examiners was serving a term in a federal penitentiary for having been "unlawfully concealing assets from the United States Government, for making a false oath in respect to his assets and for perjury. He had been previously convicted of a felony, 'nolo contendere'." The basis of the court's decision was that under the New Jersey law he had not been "convicted" whereas it is a crime to be found guilty or had been found guilty after a trial and not guilty. He would have been considered as a convict of a crime involving "moral turpitude" and the Board of Medical Examiners would have been within its statutory rights in revoking his license. The order of the Court of Errors and Appeals seems difficult to reconcile with common sense. Now who can protect the public against this charlatan? Obviously any one with a lustrous record, such as that of Schirson, should never have been granted a license in the first place!

POSTWAR DANGERS OF TROPICAL PARASITIC DISEASES

The section of parasitology of the New York Academy of Sciences held a conference last March on parasitic diseases in relation to the war. Current and postwar problems associated with tropical and parasitic diseases were considered.¹ At the end of his discussion of the clinical features of tropical parasitic diseases in war operations Lieutenant Colonel Mackie of the Army Medical School, Washington, D. C., emphasized the postwar dangers from those diseases in the United States. He said:

It is inevitable that numerous carriers and individuals with latent infections will be scattered over the country following demobilization. Certain of these conditions will be transmissible and will subsequently appear in persons who have not been out of the country. Furthermore, the clinical picture attending the combination of familiar endemic disease such as pneumonia with one of these less familiar parasitic infections may be most bizarre and atypical. Each obscures the characteristic features of the other. Contrary to the classic dictum of medical teaching against multiplicity of diagnoses, it must be recognized a priori that such multiplicity will occur and must be promptly recognized. There is urgent need for the inclusion of much more parasitology and tropical medicine in the curricula of our medical schools.

In the discussion the suggestion was made that medical schools should insist on entomology and parasitology as part of the entrance requirements, also that principles of biology might well be taught in colleges from the study of parasites and their vectors rather than from

the more conventional entomology. The menace of tropical diseases in the postwar period presents a challenge to medical schools, public health agencies, medical societies and individual physicians.

THE ETIOLOGY OF HYPERTENSION

Significant studies from this country, England and Argentina have focused attention on renal ischemia and a resulting humoral mechanism as a significant factor in the etiology of "essential hypertension." Many clinical workers have been skeptical of claims that renal ischemia is the only factor involved. Now important evidence is presented by Gregory, Lindley and Levine¹ that essential hypertension may be a general symptom which may be caused by vasomotor as well as renal factors. These Texas investigators show that spinal anesthesia, which has little effect on the blood pressure of normal people, may produce a profound fall in the blood pressure of patients with essential hypertension. Correction of renal ischemia in experimental hypertension produced by the Goldblatt method is followed by a fall of elevated blood pressure after several hours or days. Spinal anesthesia, however, produces a fall in blood pressure of patients with essential hypertension within a few minutes. When the local anesthetic action has worn off, the blood pressure of hypertensive patients returns in a few moments to the usual level for those patients. This rapidity of action suggests a nervous mechanism. The functional integrity of the peripheral vasoconstrictor apparatus of such hypertensive patients is shown by the usual vasoconstrictor action of epinephrine at a time when their blood pressure is at the lowest levels as a result of the spinal anesthesia. Essential hypertension may apparently have a vasomotor cause of central nervous system origin as well as a possible humoral cause involving the kidneys.

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

The Annual Congress on Medical Education and Licensure will be held in the Palmer House in Chicago, Feb. 14 and 15, 1944. The program for the first day will be under the auspices of the Council on Medical Education and Hospitals of the American Medical Association, for the second day under the auspices of the Federation of State Medical Boards. At the first annual conference of the Council on Medical Education in 1902 its chairman, Dr. Arthur Dean Bevan, reported "Your committee finds that the American Medical Association was founded for the purpose of elevating medical education in the United States" and that "this is still the most important function of the American Medical Association." The annual congress has exerted a powerful influence in improving the quality of medical education. The current important problems lend special significance to this next congress. All who are concerned with medical education in wartime and in the peace to follow should plan to attend.

MEDICINE AND THE WAR

In this section of *The Journal* each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeons General of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

ARMY

DISTINGUISHED SERVICE MEDAL TO GENERAL MAGEE

By direction of the President, a Distinguished Service Medal was awarded by the War Department to Major General James C Magee, United States Army, "for exceptionally distinguished and meritorious service in a position of great responsibility as Surgeon General of the Army for four years terminating May 31, 1943." The citation states: "His far-sighted and dynamic energy was greatly responsible for our soldiers being able thus far to emerge from battle with the lowest mortality rate among the wounded in our history. The Army has benefited greatly from his eagerness to avail himself of the most expert advice and data from the civilian medical profession in the fields of research against epidemics. General Magee foresaw and prevented a dangerous shortage of surgical instruments by pressing the development of domestic manufacture, resulting in an ample supply and improved quality of these vital materials. Under his guidance the Army's battle against the acquisition of venereal disease produced the lowest rate of infection in the Army's history."

AVIATION MEDICAL EXAMINERS

Graduation exercises were held at the School of Aviation Medicine, Randolph Field, Texas, on October 7 following completion of the course for aviation medical examiners. The didactic portion of the course was conducted at the School of Aviation Medicine, Randolph Field, Texas, and the practical portion of the course at the three army air forces classification centers. The list of students graduating follows:

ALABAMA		Milton Lerner 1st Lieut , Olive View	
John L Branch Major, Mont gomery		Frank E Lones, Captain Paso Robles	
William DeVlaming Captain Birmingham		Robert G Lukens 1st Lieut Sanitarium	
Archibald M Gaulocher Captain, Montgomery		William W Mills 1st Lieut , San Mateo	
Virgil S Gully 1st Lieut Butler		Carl E Nemethi, 1st Lieut , Los Angeles	
Bennett J LaCour Jr Captain Birmingham		Edmund W Overstreet Captain San Francisco	
ARIZONA		Glenn A. Pope, Captain Oakland	
Frederick W Knight Captain Sanford		Thomas B Rhone, Captain Orange	
ARKANSAS		Phillip E Svec 1st Lieut , Los Angeles	
Ross Bizzell Captain Little Rock		Neville T Ussher, Major, Santa Barbara	
William M Woods Captain Huntington		Richard W Walt, Captain San Bernardino	
CALIFORNIA		Frank W Wilks Captain Hagginswood	
John H Austin 1st Lieut Banning		William T Zimmermann, Captain Los Angeles	
Howard F Evans 1st Lieut , Beverly Hills		COLORADO	
Robert H Finley Jr Captain San Francisco		George M Harrison 1st Lieut Denver	
Antonio J Franzl Major San Francisco		Frank B Olsen 1st Lieut Urayan	
Walter W Herrmann, Major Grass Valley		Howard C Smith Captain Colorado Springs	
Nathan S Hunt Captain Los Angeles		CONNECTICUT	
William S Jreten Captain Tulare.		Donald L. Ferris Captain, Greenwich	
Samuel A Irvin Captain Los Angeles		John S Hathaway Captain New Haven	
Richard B Jones Major San Francisco		Charles E. Windus, Captain New Haven	
Richard V Lee 1st Lieut Col Palo Alto

MEDICAL UNIT BEHIND FRONT LINES

With the Fifth Army in Italy and within sight and sound of the battle, a group consisting of 22 doctors, 18 nurses and 58 enlisted men in the U. S. Army is working immediately behind our front lines doing major operations that are saving the lives of many American soldiers. This field hospital, under the command of Major Samuel A. Hanser of St. Louis and his administrative officer Lieut. Robert Bremmman of Harrisburg, Pa., is divided into three platoons which leap frog each other as the army advances. Dr. Hanser has taken the three platoons of 6 doctors and 6 nurses each, and 2 roving surgeon specialists, to within a few miles of the front to handle severely wounded cases. When a man is hit the litter bearers and first aid men search him out and he receives what treatment the field dressing station affords. If his condition is such that he is able to ride over roads cut into ruts and ruts by bombs and mines, he will be taken by ambulance to the evacuation hospital, 10 or 15 miles behind the lines. However, if he is suffering from shock or loss of blood or exposure, or is so severely wounded that he cannot survive that ride, he will be taken the 2 or 3 miles to the field hospital, where he can get instant expert attention. Although the hospital is equipped with the materials and instruments of a large city hospital, these doctors and nurses eat and sleep in unfloored tents and work under the most difficult circumstances. While the new emergency field service loses more men than other hospitals because it receives the most serious cases, its courageous staff has the great satisfaction of knowing that hundreds of lives are being saved through its work.

VETERAN ARMY NURSE DIES AT
WALTER REED HOSPITAL

The War Department announced on September 10 the death of Major Emily H. Weder, Army Nurse Corps, assistant to the principal chief nurse at Walter Reed General Hospital, Washington, D. C. Major Weder, formerly of Philadelphia entered the Army Nurse Corps on Jan. 5, 1918.

CAPTAIN LAYDEN AWARDED
VALOR MEDAL

Capt Milton J Layden, flight surgeon in the Army Air Force, has been awarded the Soldier's Medal for valor. The citation which accompanied the award said "The Soldier's Medal is being awarded for the outstanding heroism of Captain Layden in the face of imminent danger. He voluntarily rendered heroic assistance at the scene of an appalling disaster occasioned by a terrific explosion of bombs. Trucks loaded with bombs were burning furiously, but despite the danger of imminent explosion Captain Layden labored to give all possible aid and assistance to the injured. Charred and maimed bodies were treated unmindful of the warning given him that further explosions would occur. He was forced to withdraw by order of superior authority. The heroism, valor and courage in the

face of great danger reflects great credit on Captain Layden and the armed forces of the United States." Dr Layden graduated from the University of Maryland School of Medicine and College of Physicians and Surgeons Baltimore, in 1939. He enlisted in the army in October 1940 and received his wings from the School of Aviation Medicine, Randolph Field Texas.

PRISONER OF THE JAPANESE

According to information received by his father and published in the *Detroit Free Press* September 18, Capt Robert K Whiteley, formerly of Detroit, is being held a prisoner of war by the Japanese in the Philippine Islands. Captain Whiteley graduated from the University of Michigan Medical School, Ann Arbor, in 1933.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS,
DENTISTS AND VETERINARIANSHOSPITALS NEEDING INTERNS
AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their Procurement and Assignment Service quotas for Jan 1, 1944

1 Prospective interns who have not yet obtained a hospital appointment should communicate with these institutions either directly or through the office of the dean of their medical school. Assistant residents and residents should direct their applications to the hospital superintendent in the usual manner.

2 Institutions having a shortage of interns or residents are again invited to make their needs known to the Council on Medical Education and Hospitals. In reporting shortages, hospitals should indicate the number of interns, assistant residents and residents needed to complete their quotas for Jan 1, 1944.

Hospitals Reporting Vacancies for
Interns or Residents

(Continuation of list in THE JOURNAL November 13 pp 707-708)

CALIFORNIA

St Joseph's Hospital San Francisco Capacity 289 admissions 7 014
Sister Mary Raymond R N Superintendent (interns 2 residents)

CONNECTICUT

St Vincent's Hospital Bridgeport Capacity, 325 admissions, 9 000
Sister Louise Superintendent (3 interns)

ILLINOIS

Belmont Community Hospital Chicago Capacity 125 admissions, 3 399 Mrs Gertrude T Scofield Superintendent (3 interns)
Fingewood Hospital Chicago Capacity 187 admissions 5 263 A R Zutter Superintendent (4 interns)
Hospital of St Anthony de Padua Chicago Capacity, 269 admissions 7 041 Sister Alberta R N Superintendent (3 interns)
St Bernard's Hospital Chicago Capacity 242 admissions 7 401 Mother Cecelia Murray R N Superintendent (intern)
St Elizabeth Hospital Chicago Capacity 307 admissions 10 777 Sister M Vetusa Superintendent (3 interns)

INDIANA

St Joseph's Hospital South Bend Capacity 192 admissions 4 494
Sister Mary Ellen R N Superintendent (2 interns)

KENTUCKY

St Mary and Elizabeth Hospital Louisville Capacity 205 admissions 4 817 Sister Ludovica R N Superintendent (intern)

MAINE

1st Maine General Hospital Bangor Capacity 243 admissions 5 467 Dr Allan Craig Medical Director (4 interns)

MARYLAND

Maryland General Hospital Baltimore Capacity 264 admissions 5 509 Stuart B Crawford Superintendent (6 interns)

MICHIGAN

St Joseph's Mercy Hospital Ann Arbor Capacity 250 admissions 5 971 Sister M Philippa Superintendent (interns residents)
Saginaw General Hospital Saginaw Capacity 166 admissions 4 896 Kate J Harl Superintendent (2 interns)
St Mary's Hospital Saginaw Capacity 204 admissions 5 318 Sister Electa P N Superintendent (2 interns 1 resident)

MINNESOTA

St Mary's Hospital Minneapolis Capacity 320 admissions 9 291
Sister M Conchessa Superintendent (6 interns)

MISSOURI

St Joseph's Hospital St Joseph Capacity 168 admissions 3 023
Sister Emily R N Superintendent (1 intern 1 resident)
St Louis City Hospital St Louis Capacity 1 127 admissions 15 013
Mr Clinton T Smith Superintendent (residents—med OB G)

MONTANA

Murray Hospital Clinic Butte Capacity 120 admissions 3 013
Mr W H Rex Business Manager (2 interns)

NEW JERSEY

St Peter's General Hospital New Brunswick Capacity 227 admissions 6 034 Sister R Ietelher, Superintendent (2 interns 1 resident)
Perth Amboy General Hospital Perth Amboy Capacity 197 admissions 4 932 Mr George C Schucks Superintendent (3 interns)

NEW YORK

The Kingston Hospital Kingston Capacity 118 admissions 2 839
Jessie P Allan, Superintendent (resident—mixed)
New Rochelle Hospital New Rochelle Capacity 309 admissions 6 516
Alex E Norton Superintendent (resident)
Jewish Memorial Hospital New York Capacity 217 admissions 4 994 Louis Miller Superintendent (3 interns)
New York Infirmary New York Capacity 160 admissions 2 595
Miss M Marion Smith Administrator (5 interns residents—Med OB Surg—women only)

OHIO

St Mary's Hospital Cincinnati Capacity 230 admissions, 5 114
Sister Theonilla R N Superintendent (4 interns)
Lutheran Hospital Cleveland Capacity 137 admissions 4 121 Lee S Lampher Superintendent (3 interns)

PENNSYLVANIA

The Woman's Hospital of Philadelphia Philadelphia Capacity 166 admissions 2 887 Dora Ruland M D Medical Director (3 interns resident—medicine)
Passavant Hospital Pittsburgh Capacity 120 admissions 2 203
Sr Martha Pretzlaff Superintendent (3 interns)
Sewickley Valley Hospital Sewickley Capacity 185 admissions 3 931
Miss Helen Pratt Superintendent (4 interns)

RHODE ISLAND

Charles V Chapin Hospital Providence Admissions 760 (psy) Dr William Hindle Superintendent (resident—psychiatry)

TENNESSEE

St Joseph Hospital Memphis Capacity 297 admissions 8 670
Sister M Sponsaria Superintendent (4 interns)

UTAH

St Mark's Hospital Salt Lake City Capacity 164 admissions 4 286
O V Wardrop Superintendent (4 interns)

VIRGINIA

Norfolk General Hospital Norfolk Capacity 333 admissions 9 584
Mr W P Earney Superintendent (interns)

WASHINGTON

Sacred Heart Hospital Spokane Capacity 368 admissions 9 274
Sister Henrietta Superior (8 interns)
St Joseph's Hospital Tacoma Capacity 344 admissions 6 853 Sister M Patricia Francis (interns)

WEST VIRGINIA

Wheeling Hospital Wheeling Capacity 236 admissions 4 587 Sister Mary Ruth Administrator (interns)

ORGANIZATION SECTION

BRITISH MEDICAL ASSOCIATION ON BEVERIDGE PLAN

The government has promised to issue a "white paper" setting forth the official proposals in regard to the medical provisions of the Beveridge report and to give opportunity for full discussion by the medical profession before any legislation is enacted. Thus "white paper" had not appeared when the annual representative meeting of the British Medical Association, which is comparable to the House of Delegates of the American Medical Association met September 21-23. Although much of the time of the meeting was given to discussion of 'The Future of Medical Services,' there was no definite legislative proposal available for consideration, and action was limited to statements of principles and general positions. The attitude of the meeting was shown by a vote of 200 to 10 in favor of the resolution that 'In the opinion of the Representative body the creating of a whole time salaried state medical service is not in the best interest of the community.'

The Representative Committee, which had been appointed to study the whole subject and which had previously submitted a report, presented its recommendations, which, with some amendments, were adopted in the following form:¹

(A) (To be embodied in a preamble recalling the principles set out in the 'General Medical Service for the Nation')
1 The system of medical service should be directed to the achievement of positive health and the prevention of disease no less than to the relief of sickness. 2 There should be available for every individual the services of a general practitioner or a family doctor of his own choice. 3 Consultants and specialists, laboratory services, and all necessary auxiliary services, together with institutional provision when required, should be available for the individual patient, normally through the agency of the family doctor. 4 The several parts of the complete medical service should be closely coordinated and developed by the application of a planned national health policy acceptable to the profession as a whole.

(B) The health of the people depends primarily on the social and environmental conditions under which they live and work, on security against fear and want, on nutritional standards, on educational facilities and on the facilities for exercise and leisure. The improvement and extension of measures to satisfy these needs should precede or accompany any future organization of medical services.

(C) The efficiency of a country's medical services, both preventive and curative, depends on the available medical and scientific knowledge on the character and extent of medical education on the sufficiency and quality of personnel on facilities for treatment and on the absence of any economic barriers that impede the utilization of such services. Thus, in order to improve the country's medical services, the facilities and resources for medical research should be greatly increased and methods devised for their adequate application, medical education both undergraduate and postgraduate should be maintained on a high standard and be adapted to modern needs, there should be sufficiency of personnel and institutional accommodation, and wherever economic barriers prevent an individual taking advantage of medical services such barriers should be removed.

(D) Subject to these general and overriding considerations, the functions of the state should be to coordinate existing provision both official and nonofficial, to augment it where necessary and to secure that it is available without economic barrier to all who need it. The state should confine itself within these wide limits invading the personal freedom of both citizen and doctor only to the extent which the satisfaction of these functional demands.

(I) It is not in the public interest that the state should convert the medical profession into a salaried branch of central or local government service. The state should not assume control

of doctors rendering individual or personal health service. The profession rejects any proposal for the control of the future medical service by local authorities as at present constituted.

(J) Free choice as between doctor and patient should be preserved as a basic principle of future health services and no administrative structure should be approved which does not both permit and encourage such free choice.

(G) It is not in the public interest that the state should invade the doctor-patient relationship. The loyalty and obligation of a doctor rendering personal health service to an individual patient should be to that patient and to none other.

(H) Free choice of doctor should be reinforced by a method of remuneration which relates remuneration to the amount of work done or the number of persons for whom responsibility is accepted.

(I) Every member of the community should be free to consult the doctor of his choice either officially as when he consults the doctor he has selected under an official service, or privately, as when he consults some other doctor, whether that doctor is a member of an official service or not. Nothing should be done to encourage the splitting of the medical profession into two groups—the official doctors and the nonofficial doctors.

(J) Consultants and specialists should normally be attached to the hospital. For those persons who wish to be treated in private accommodations, whether part of a hospital or not, private consulting practice should continue.

(K) The central administrative structure should be a corporate body concerned only with civilian health services and should be responsible for all civilian health services. This central administrative body should be advised on medical matters, including personnel, by a medical advisory committee representative of the medical profession which should be at liberty to publish its findings. Locally, new administrative bodies, responsible to the central authority, should cover wide areas and should be representative directly or indirectly of the community served and in appropriate proportion, of the local medical profession and voluntary hospitals. They should be advised on medical matters, including personnel, by local medical advisory committees representative of the local medical profession which should be at liberty to publish their findings. These administrative changes should be regarded as foundation changes to be agreed before other changes are initiated.

(L) All branches of medical practice should be regarded as a single service, and it is undesirable that a detailed scheme for general practitioners should be framed and put into operation without corresponding arrangements for other branches of practice.

(M) Pending the consideration and completion of the foundation administrative changes mentioned in K, as a step toward the satisfaction of assumption B there should be extension of national health insurance to include dependents of insured persons and others of like economic status and to cover consultant and specialist services and laboratory and hospital facilities as well as general practitioner service. The service should be improved from time to time as recommended by the profession. Those persons with incomes above an agreed limit could if Parliament decides to make the service available to every member of the community be permitted to become voluntary contributors to the extended service. A reconstruction of insurance committees would be necessary.

(N) There should be initiated by arrangement and agreement between the government and the profession, organized experiments in the methods of practice, such as group practice, including health centers of different kinds which should extend to general practitioner hospital units attached to general hospitals. Future developments in group practice should depend on the results of such clinical and administrative experimentation.

CALIFORNIA

Dr William Dock Named Professor of Medicine—Dr William Dock, since 1940 professor of pathology at Cornell University Medical College, New York, has been appointed professor and chairman of the department of medicine at the University of Southern California School of Medicine Los Angeles. Prior to joining the Cornell faculty, Dr Dock was assistant professor of medicine at Stanford University School of Medicine and later professor of pathology.

Typhoid Grandmothers—The Los Angeles City Health Department has reported recently that, of 21 cases of typhoid reported to that department in the last sixteen months, 11 have been traced definitely to carriers, according to *California's Health*. In 10 of these 11 cases, the infection had been acquired from grandmothers. It is suggested that several factors may be involved (1) that these grandmothers lived through a period in which typhoid was rampant in the United States (2) that grandmothers are frequently active in the preparation of food in the home and (3) that they lived in a day and age when sanitation was not considered of as great importance as it is considered today. It is known that about 2 per cent of persons who have typhoid become permanent carriers. In the course of the department's investigation it was found that a 68 year old grandmother who had typhoid at the age of 17 was responsible for 4 cases of the disease that appeared within her immediate family during the last forty years, 1 of which resulted fatally.

GEORGIA

Personal—Dr Young H. Yarbrough, assistant superintendent of the Milledgeville State Hospital, Milledgeville, has been appointed medical superintendent to succeed Dr Lovick P. Longino, effective September 1. The latter, who has been connected with the hospital since 1906, resigned because of ill health.

ILLINOIS

License Restored—The Illinois State Board of Registration in Medicine has restored the license to practice medicine in Illinois of Dr Delbert R. Blender, Chicago. Dr Blender's license had been revoked on June 22.

Chicago

Annual Meeting of Institute of Medicine—The twenty-eighth annual meeting of the Institute of Medicine of Chicago will be held at the Palmer House December 7. Dr Frederick B. Noyes will deliver the presidential address on "Personal Recollections of a Leader, Greene Vardaman Black. His Development and Influence."

Changes in the Faculty at Loyola—George F. Simmons, Ph.D. and Arthur J. Gatz, Ph.D., are among the new appointments to the Loyola University School of Medicine. Promotions at the school include:

David S. Jones, Ph.D. to assistant professor of anatomy
Dr John L. Keeley to associate clinical professor of surgery
Dr Mary C. Patras to assistant professor of physiology
Dr George A. Hellmuth to assistant clinical professor of medicine
Dr Leo A. Kaplan to assistant clinical professor in neurology and psychiatry

Alumni Election—On November 4, Dr Howard B. Carroll was reelected president of the Northwestern University Medical Alumni Association for the third term. Other officers are Drs Clarence G. Shearson, vice president in charge of foundation and century plan; Frederick W. Merrifield, vice president in charge of activities; Sumner L. S. Koch, vice president in charge of achievement; Everett C. Moulton, Fort Smith, Ark., vice president in charge of placements; Samuel C. Stanton, Hinsdale, Ill., secretary; and Harold E. Davis, secretary and treasurer.

Dr Piszczek Surveys Poliomyelitis Epidemic Areas—At the request of the National Foundation for Infantile Paralysis, Dr Edward A. Piszczek, director of the Cook County Public Health Unit, started on November 1 to survey the states included in the recent poliomyelitis epidemic areas. The purpose of the survey is to observe the treatments and treatment facilities in the various areas with the objective, it is reported, of standardizing the treatment. The states which Dr Piszczek will visit include Kansas, Colorado, Utah, Washington, Oregon, California, Arizona, Texas, Oklahoma and Arkansas.

KENTUCKY

First Annual Meeting on Mental Hygiene—The Kentucky Mental Hygiene Association held its first annual meeting in Louisville on November 19. On September 25 the society held the first statewide mental hygiene meeting in Kentucky, also in Louisville, at which Dr Edward I. Francis, associate professor of psychiatry, University of Louisville School of Medicine discussed a general mental hygiene program and emphasized the importance of public and private organizations working together and the collaboration between educational, professional and religious groups. Other speakers on the program included W. A. Frost, state commissioner of welfare; Dr S. Sprafford Ackerly, director of the mental hygiene clinic, Louisville; Dr Addie M. Lyon, Frankfort, director of the state division of hospitals and mental hygiene; and Dr Isham Kimbrell, superintendent of the Central State Hospital, Frankfort. Rev. George J. O'Brien, chaplain of St. Joseph Hospital, Lexington, is president of the state mental hygiene association. Since the organization of the state group, seven counties have already become represented in its membership. Fayette County has organized the first county unit with headquarters in Lexington. Jefferson County, which has the largest population of any Kentucky county, has a representation of 23 members who contemplate early organization of a unit in Louisville. The Kentucky Mental Hygiene Association was organized in response to a request made by Dr Lyon in his address before the Kentucky Psychiatric Association in Louisville in January 1942 in which he emphasized the need for a mental hygiene association that would extend into every section of the state with a program that could be adapted to the needs and resources of the varying communities. Membership in the association is composed of lay and professional persons who are interested in promoting mental health. There are three classifications of members: active members who pay an annual membership fee of \$1.50 (50 cents of which is returned to the county unit), patron members who contribute \$100 or more, and honorary membership conferred by a two thirds vote of the membership. All members enrolling within the first twelve months are charter members.

MARYLAND

Fifty Years of Medicine at Johns Hopkins—On October 2 Johns Hopkins University School of Medicine, Baltimore, observed its fiftieth anniversary. In view of the war no formal exercises were held to celebrate the event, instead a booklet was published and distributed to graduates and friends of the school as a memento of the occasion. The booklet contains a brief account of the founding of the school and its achievements during the last fifty years and photographs of illustrious physicians and scientists present and former members of the staff, who participated in the school's progress. It discusses the development of the various departments individually and the scope of the school as a whole, pointing out that the opening of the medical school marked a new departure in medical education in America because it was the first medical school in this country to open with all its professors in the preclinical branches on a full time or university basis.

MICHIGAN

University Awards Kellogg Prize—Dr Henry E. C. Everett, a member of the 1943 graduating class, University of Michigan Medical School, Ann Arbor, was recently presented with the Kellogg Medical Prize for highest scholastic achievement. Dr Everett will serve his internship at the City Hospital, Cleveland.

Physicians Required at High School Football Games—The Detroit Board of Education requests attendance of a physician at every high school football game. Compensation has been provided and a schedule has been set up. The need for physicians at these games was published in the form of a request in the *Detroit Medical News*.

Special Meeting to Discuss Wagner-Murray-Dingell Bill—The Wayne County Medical Society has called a special meeting for November 29 to discuss the Wagner-Murray-Dingell legislation. The students of Wayne University College of Medicine, Detroit, have been invited to attend the meeting as well as intern and resident staffs of local hospitals.

State Medical Board Changes—Dr Elmer W. Schnoor, Grand Rapids, was elected president of the Michigan State Board of Registration in Medicine for a third term at an annual meeting of the board in Lansing. Dr David C. Eisele, Ironwood, has been named a member of the board to succeed Dr Andrew C. Roche, Calumet, for a four year term expiring Sept. 30, 1947.

NEW JERSEY

Emergency Hospital Unit Created—The second public health unit in the program to organize affiliated hospital units of the Emergency Medical Service of the U. S. Office of Civilian Defense was established at the Newark Beth Israel Hospital recently. The first unit was created in the Albany Hospital, Albany, N. Y. The project is under the auspice of the U. S. Public Health Service and covers the activation of physicians, nurses, dentists and other health workers for the armed forces, and for the treatment of civilian emergencies or in case the flow of medical aid from the various theaters of war overtaxes the regular civilian hospital. Under the plan the participating hospitals are organized in a unit of the U. S. Public Health Service.

NEW YORK

Personal—Dr. Frederick G. Klump, president of the Winthrop Hospital, Long Beach, Cal., received the Distinguished Service Award from the Philadelphia College of Podiatric Medicine in recognition of his "distinguished service to the medical community."

Graduate Lecture—The New York Medical Society and the state medical society presented a graduate lecture on "Rheumatic Fever" by Dr. H. H. Dreyer, before the Jefferson County Medical Society, Westchester, November 11. The lecture was given by Dr. Dreyer, professor of clinical medicine, Syracuse University College of Medicine, Syracuse.

New York City

Course in Occupational Dermatoses—A lecture course on occupational dermatoses will be held at the New York Academy of Medicine, December 11 under the auspices of the dermatoses investigations division of industrial hygiene, National Institute of Health, Public Health U. S. Public Health Service. Dr. S. J. Davis, medical director, U. S. P. H. S., chief of the division of dermatoses investigation, and the following members of his staff will deliver the lectures: Samuel M. Peck, senior surgeon; John L. Dunn Jr., surgeon; James Q. Gint Jr., surgeon; and Howard S. Mason, associate chemist. James G. Townsend, medical director, chief of the division of industrial hygiene, National Institute of Health will deliver the opening address. All are of the U. S. P. H. S.

Lectures to the Public—The New York Academy of Medicine started its ninth series of lectures to the public on November 18 with the presentation of the Lusk R. Williams Memorial Lecture by Sir Gerald Campbell, British minister and special assistant to the British ambassador, on "Effect of Science on Human Bombs." Other lectures in the series are: Lieut. Col. Howard T. Mackie, M. C., A. U. S., "Epidemics and War," December 14; Charles Glen Kim, Ph.D., New York, "The Ninety Fourth Anniversary of the New York Academy of Medicine Food and Civilization," January 27; Dr. Reinhold Fitz, Boston, "Medicine and the Changing World," February 24; Dr. Colin M. MacLeod, New York, "The Past Present and Future of Chemotherapy," March 23; Dr. Edward A. Stricker, Philadelphia, the George R. Siedenburg Memorial Lecture, "How We Averted the Rule of King Mob," April 27.

Clement Cleveland Award Goes to Frederick Hoffman—On November 2 the Clement Cleveland Award for 1943 was awarded in absentia to Frederick L. Hoffman, LL.D., San Diego, for many years consulting statistician and a third vice president for the Prudential Life Insurance Company, Newark, N. J. The medal, which is presented for "outstanding service in the cause of cancer control," was received for Dr. Hoffman by Dr. Howard C. Taylor, who in his acceptance address stemmed the beginning of the national society to a paper read by Dr. Hoffman on May 7, 1913 at a meeting of the American Gynecological Society. An exhibit at the meeting also credits Dr. Hoffman with the development of this movement. The annual dinner of the New York Cancer Committee was given this year in honor of the founders of the American Society for the Control of Cancer. The speakers included Clarence C. Little, Sc.D., managing director, who reviewed the national organization's history.

New City Division of Nutrition—The New York City Department of Health has created a new division of nutrition and appointed eight nutritionists to supervise the intensified nutritional program of the health department which has been necessitated by the war and current food shortages. Mrs. Gertrude Gates Mudge has been named supervising nutritionist. According to Dr. Ernest L. Stebbins, city health commissioner, one of the projects to be conducted will be the development of a staff education program for physicians and nurses in the health department. Specialized nutrition instruction will be provided with emphasis on timely food information which the

physicians and public health nurses can pass on to their patients and to persons with whom they come in contact during their professional visits. Working through the health department's district health centers, the nutritionists will also cooperate with public and private social and welfare agencies and the New York City food and nutrition program in the development of neighborhood programs throughout the city.

OHIO

One Hundred Years of Medicine—The Cleveland Health Museum has given over its entire second floor to an exhibit reviewing the last hundred years of medicine in Cleveland as a part of the centennial celebration of Western Reserve University School of Medicine. Dr. Howard Dittick, director of the museum of historical medicine of the Cleveland Medical Library Association, is in charge of the display. Instruments, books, etc. bills and documents of the country doctor of a hundred years ago feature the exhibit. A preview was held on October 26 under the sponsorship of the Western Reserve Historical Society, the Museum of Historical Medicine of the Cleveland Medical Library Association and the Cleveland Health Museum. Chauncey D. Leake, Ph.D., dean of the University of Texas Medical Branch, Galveston, spoke on "Milestones in Medicine." The office of a Cleveland doctor, Abner Webb, 1846, is reconstructed with the help of old letters and prints and with many of his own furnishings. A news item announcing the centennial program appeared in THE JOURNAL, October 16, page 430.

OKLAHOMA

Portrait of Dr. Garabedian—A portrait of the late Dr. G. A. Z. Garabedian has been presented to the Tulsa County Medical Library by Mrs. Garabedian. The work was executed by Diane Travis and recently was hung at Hillcrest Hospital. An endowment fund bearing the name of the late physician was established shortly after his death in 1938 by Mrs. Garabedian.

The Annual Leroy Long Lecture—Dr. Harry L. Alexander, professor of clinical medicine, Washington University School of Medicine, St. Louis, presented the fourth annual Leroy Long Memorial Lecture at the University of Oklahoma School of Medicine, Oklahoma City, recently on "The Present Status of Chemotherapy in the Treatment of Diseases." The lecture is sponsored by the alumni and undergraduates of Phi Beta Kappa as a memorial to the late Dr. Leroy Long, Oklahoma City, dean of the medical school from 1915 to 1931.

OREGON

Meeting on Poliomyelitis—The University of Oregon Medical School, Portland, and the Multnomah County Chapter for Infantile Paralysis recently held a symposium on the newer concepts of the management of poliomyelitis. The course was designed to help in handling existing cases. Only basic data were presented. Speakers included Mr. E. T. Hedlund, postmaster, and Drs. Adolph Weinzierl, Paul V. Woolley Jr., Lawrence Noall and Lewis D. Clark.

PENNSYLVANIA

Physician Observes Ninety-Third Birthday—Dr. George B. Woods, Washington, celebrated his ninety-third birthday, September 7. For the past sixty-nine years Dr. Woods has practiced in Washington County and for more than thirty years has been physician to the Washington County Home and Poor Farm, a position he still holds, having given up all other practice.

State Psychiatric Meeting—Dr. George W. Smeltz, Pittsburgh, was named president-elect of the Pennsylvania Psychiatric Society at its fifth annual dinner meeting in Philadelphia, October 7, and Dr. Ralph L. Hill, Wernersville, was installed as president. Dr. Le Roy M. A. Maeder, 206 South 13th Street, Philadelphia 7, is the secretary-treasurer. Speakers included Mr. John Corcoran, radio commentator and writer, who discussed "Today," and Dr. Oliver Spurgeon English, Philadelphia, "The Referral Center for Selective Service in Philadelphia."

Philadelphia

The Pancoast Lecture—Dr. Dallas B. Phemister, Thomas D. Jones professor of surgery, University of Chicago School of Medicine, delivered the annual Pancoast Lecture of the Philadelphia Roentgen Ray Society, November 4, on "Disturbances Arising from Interruption of Circulation in the Skeletal System." The lectureship was established in 1941 in honor of the late Dr. Henry K. Pancoast, professor of radiology at the University of Pennsylvania School of Medicine.

Trust Fund for Needy Patients Established—William H. Donner, retired industrialist, has given a \$400,000 trust fund to the University of Pennsylvania to establish the Donner Fund for Needy Patients. The income from the fund will be used to extend to needy patients special facilities additional to those normally supplied by the hospital. Part of the income may be used for assistance in clinical research problems and for special experiments in those aspects of hospital administration that have to do principally with the welfare of patients. Surveys may be conducted, investigations of routine practices made and further special training of personnel undertaken, including grants to graduate fellows in nursing, and, for trial periods, new administrative procedures that have direct bearing on the welfare of the patients may be developed. The specific objective of the fund is to assist needy patients who require extraordinary services not usually supplied by a hospital. Mr. Donner gave \$2,000,000 in 1932 to found the International Cancer Research Foundation, Philadelphia.

Professorship of Medicine to Be Created—The Frank Wister Thomas Professorship of Medicine is to be established at the University of Pennsylvania School of Medicine under the will of Mrs. Maria G. B. Thomas of Philadelphia, who died on September 15 according to the *Pennsylvania Medical Journal*. The professorship will be a memorial to Mrs. Thomas's husband Dr. Frank W. Thomas who died on Jan. 19, 1928. According to the will, most of the \$200,000 estate is left ultimately to create the new chair. The residue is bequeathed to the university toward the endowment, and trust funds amounting to \$50,000 will be added to it as the beneficiaries die, until \$200,000 is accumulated. The holder of the professorship shall be the person who is recognized by the trustees as the head or chief professor of medicine at the medical school. If the endowment exceeds the amount necessary to establish the professorship or if the chair becomes temporarily vacant one or more temporary Frank Wister Thomas fellowships in medicine are to be set up. Any excess over the \$200,000 limit fixed for the professorship is bequeathed to Germantown Dispensary and Hospital.

SOUTH CAROLINA

State Venereal Hospitals to Be Relocated—Relocation of two of the state's three venereal disease hospitals to place all closer to Columbia was announced in newspaper reports recently. The Pontiac quarantine hospital for white women will be moved to Camp Victory, about 12 miles from Columbia and the hospital for Negro women at Goldville will be moved to the old Pontiac site. The third hospital at the state prison for women will remain unchanged. The move was to be made during October.

TENNESSEE

Memorial Health Unit Established—Dr. Warren C. Ramer, Lexington, has been placed in charge of the Blanche Bomer Morgan Memorial Health unit in Haywood County dividing his time between this unit and those in Lauderdale and Tipton counties. The Blanche Bomer Memorial Unit was established in Brownsville through the offer of L. W. Morgan to contribute \$2,000 a year for a period of five years in memory of the late Mrs. Morgan, who had been interested in health education particularly the campaign against tuberculosis. The unit's first public function was a tuberculosis clinic.

VIRGINIA

Graduate Course—The Virginia Society of Ophthalmology and Otolaryngology will sponsor its tenth annual postgraduate course December 7-10 in the Burch Auditorium of the Medical College of Virginia, Richmond. Among the speakers will be Drs. Oscar V. Batson, Philadelphia, Leroy A. Schall, Boston, Henry B. Orton, Newark, N. J., Warren T. Vaughan, Richmond, John A. Kolmer, Philadelphia, Ferris Smith, Grand Rapids, Mich., John J. Shea, Memphis, Tenn., Edmund B. Spruth, Philadelphia, Peter C. Kronfeld, Chicago, Algernon B. Reese, New York, Ramon Castroviejo, New York, and Theodore L. Terry, Boston.

State Hospital Physicians Win Research Awards—First prize of \$225 in the annual competition inaugurated early this year by the Virginia State Hospital Board went to Drs. Isadore S. Weiss and Walther Reese of the Eastern State Hospital, Williamsburg, for their Preliminary Report of the Study of 200 Autopsy Cases at the Eastern State Hospital with Special Emphasis on Neuropathology and Brain Tumor in Old Age. Dr. Simon Coren, Central State Hospital, Petersburg, received \$125 for his Analysis of the Negro Criminal Insane in Virginia. Dr. Vincent L. Lascara, Central State Hospital, received

\$50 for his work on "Neurosyphilis with a Two Year Observation of the Comparative Therapeutic Effects of Inoculation Malaria and Artificial Fever Therapy." The state hospital board made the awards at its October 14 meeting. The prize winners were rated according to their merit by Dr. Winfred Overholser, St. Elizabeths Hospital, Washington, D. C. Early this year the state hospital board arranged to make financial prizes available annually to stimulate interest in professional work among physicians on the staffs of the state hospitals exclusive of the superintendents. The prizes are given for original or meritorious papers, based preferably on observations of patients under the physicians' care (11th Annual February 27 p. 693). The competitive papers need not necessarily deal entirely with the clinical or laboratory features but may cover reclassification and deductions that have not heretofore been made.

Seaboard Medical Association Meeting—The forty-eighth annual session of the Seaboard Medical Association of Virginia and North Carolina will be held at Richmond, Va., November 30 to December 2, with headquarters at the Jefferson Hotel, under the presidency of Dr. Charles Lydon Harrill, Norfolk, Va. A preliminary program includes, as speakers, Gov. Colgate W. Darden Jr., Richmond and the following:

Ben Jones, American Red Cross, Camp Lee, Va. Red Cross Activities at Home and Abroad.
Dr. Antonio A. Burke, Norfolk. Remarks on Nasal Sinus Disease.
Dr. Vernon D. Offutt, Kingston, N. C. Diagnosis and Treatment of Virus Pneumonia.
Dr. Eugene J. Townsberg, Norfolk. Icterus and Dermatitis of the Temple (Gentilia).
Drs. Keith S. Grimson and Gmel B. Hodge, Durham. Intestinal Obstruction.
Dr. Jacques P. Gray, Richmond. Medical Education in Wartime.
Dr. Malory A. Pittman, Wilson, N. C. Penicillin in the Treatment of Osteomyelitis and Other Inflammations.
Dr. Donnell B. Cobb, Goldsboro, N. C. Simple Method of Fracture Fixation.
Dr. James Morrison Hutcheson, Richmond. Medicolegal Aspects of Coronary Thrombosis.
Dr. Randolph B. Crumrine Jr., Norfolk. Skin Manifestations of Sulfathiazole Intoxication.
Drs. Russell V. I. Buxton, Waverly, R. Payne and Morris B. Bleckroft, Newport News, Va. False Negative Results in the Aschheim Zondek Test.
Dr. Harry Hudnall Ware Jr., Richmond. Fetal Pregnancy.
Dr. Charles J. Andrews, Norfolk. The Maternal Mortality Situation.

The meeting will also include a symposium on "Diarrhea" with the following members of the faculty of the Medical College of Virginia, Richmond, as speakers: Drs. John H. Scherer on "Bacillary Dysentery, Amebiasis," Lee E. Sutton Jr. "Acute Gastroenteritis in Children," Thomas Dewey Davis, "Diarrhea Associated with Organic Disease of the Colon," and Maxwell Berry Jr., "Diarrhea Associated with Functional Diseases."

WEST VIRGINIA

Personal—Dr. Walter E. Vest, Huntington, was reelected president for a fourth term of the public health council of West Virginia at its meeting in Charleston, October 26. Dr. Vest has served continuously as president of the council since 1935.—E. J. Hall, Buckhannon, educator, has been named as educational consultant in venereal diseases in the state department of health.

Appointments as Health Officers—Dr. James E. Coleman, Fayetteville, has been appointed by the public health council as full time health officer of Fayette County. The council also appointed the following physicians, among others, as part time health officers:

Dr. Harry K. Owens, Elkins.
Dr. James K. Pichens, Jaeger.
Dr. Roscoe Stotts, Kenova.
Dr. Bayard L. Liggett, Mill Creek.
Dr. James A. Newcome, Keyser, Mineral County.
Dr. Ona F. Mitchell, Franklin, Pendleton County.

Venereal Treatment Center—A medical center for the treatment of venereal diseases will be opened in an abandoned National Youth Administration training center, South Charleston, to accommodate about 350 patients. A medical clinic with 35 beds will be attached and facilities for a limited amount of occupational training will be provided. Funds for the transportation, hospitalization and treatment of patients will be provided by the U. S. Public Health Service which will also provide a medical staff for the institution. Under the provisions of an act passed at the 1943 session of the West Virginia legislature local health officers are authorized to commit to the institution persons who refuse to submit to treatment in their local communities but admission will also be authorized on a voluntary basis. The so called fast treatment will be used at the center, consisting of a maximum of thirty days for syphilis and fifteen days for gonorrhea.

GENERAL

Meeting on Radiology—The Radiological Society of North America will hold a business session at the Drake Hotel, Chicago, December 1-2. There will be no scientific sessions, exhibitors or lectures. Dr. Donald S. Childs, 697 Medical Arts Building, Syracuse 2, N. Y., is secretary.

Anesthetics Convene—The American Society of Anesthesiologists will hold its annual meeting at the New York Academy of Medicine, New York, December 9-11, under the presidency of Dr. E. A. Kohn, New York. The speakers will include Dr. J. D. A. F. C. Morrison, W. A. on "The Anesthetic Control of Central Effects of Anesthesia," and Dr. J. D. A. F. C. Morrison, W. A. on "The Anesthetic Control of Central Effects of Anesthesia." The meeting will be held at the New York Academy of Medicine, New York.

American Period of Soviet Medicine—The American Society of Medical Informatics has published a special issue of *Informa*, a journal of medical information, devoted to Soviet medicine. The issue is edited by Dr. Walter B. Cannon, Harvard Medical School, Boston. It contains a number of articles by English-speaking physicians who have been in the Soviet Union. Consequently, Soviet medicine has little circulation in the English-speaking world. The publication will continue to publish papers from the Russian survey by American experts on various aspects of Soviet medicine, including current medical events in the U. S. S. R. Reviews of Soviet medical books and abstracts from Soviet medical journals. The publication will appear bi-monthly under the editorship of Dr. Henry I. Sierist.

Latin American Physicians Study Health Education—Eight Latin American physicians traveling in the United States under the auspices of the Pan American Sanitary Bureau visited the American Medical Association headquarters in Chicago, November 6-9. Their program in Chicago was arranged cooperatively by the American Medical Association and the American College of Surgeons, including visits at the headquarters of both organizations and opportunities to observe hospital work, medical education and particularly health education. The physicians, together with the seven Latin American republics they represented were as follows:

Dr. Jeanno Albuquerque, commissioner of public health of the federal district, Rio de Janeiro, Brazil.
Dr. Alferdo Marinho, director of health education, Rio de Janeiro, Brazil.
Dr. Francisco Sequeira, chief health education, San Salvador, El Salvador.
Dr. Epaminondas Quintana, chief health education division, Guatemala.
Dr. Alfonso Segura Alister, director, Morales Hospital, Mexico City, Mexico.
Dr. Carlos Amaya, chief health education, Managua, Nicaragua.
Dr. Kaul Pena, chief public health education, Asuncion, Paraguay.
Dr. M. Lores Gubillon, chief division of health education and publications, Caracas, Venezuela.

Special Society Elections—Dr. Albert C. Furstenberg, Ann Arbor, Mich., was chosen president-elect of the Association of American Medical Colleges at its annual meeting in Detroit recently and Dr. Lven M. MacEwen, Iowa City, was installed as president. Philip A. Shaffer, Ph.D., St. Louis, is the vice president, Dr. Arthur C. Bachmeyer, Chicago, treasurer, and Dr. Fred C. Zapffe, Chicago, secretary. The 1944 meeting will be held in Detroit at the Statler Hotel, October 23-25. Dr. Gordon B. New, Rochester, Minn., was chosen president-elect of the American Academy of Ophthalmology and Otolaryngology at its annual meeting in Chicago, October 10-13, and Dr. Lawrence F. Post, St. Louis, was inducted into the presidency. Vice presidents are Drs. C. Stewart Nash, Rochester, N. Y., Harold F. Whalman, Los Angeles, and Chester L. Jackson, Philadelphia. Dr. William L. Benedict, Rochester, Minn., is the executive secretary-treasurer. Other secretaries are Drs. Oliver E. Van Alyea, Chicago, for otolaryngology, Algernon B. Reese, New York, for ophthalmology, Albert D. Ruedemann, Cleveland, for instruction-ophthalmology, Dean M. Liele, Iowa City, for instruction-otolaryngology and maxillofacial surgery, Erling W. Hansen, Minneapolis, for relations and Harry S. Gradle, Chicago, for home study courses.

Finney-Howell Research Foundation Fellowships—Announcement has been made by the Finney-Howell Research Foundation, Inc., that all applications for fellowships for next year must be filed in the office of the foundation, 1211 Cathedral Street, Baltimore, by Jan. 1, 1944. Applications received after that date cannot be considered for 1944 awards, which will be made the first of March 1944. This foundation was provided

for in the will of the late Dr. George Walker, Baltimore, for the support of "research work into the cause or causes and the treatment of cancer." The will directed that the surplus income from the assets of the foundation together with the principal sum should be expended within a period of ten years to support a number of fellowships in cancer research, each with an annual stipend of \$2,000 "in such universities, laboratories and other institutions wherever situated as may be approved by the board of directors." Fellowships carrying an annual stipend of \$2,000 are awarded for the period of one year, with the possibility of renewal up to three years when deemed wise by the board of directors. Special grants of limited sums may be made to support the work carried on under a fellowship. Applications must be made on the blank form which will be furnished by the secretary, Dr. William R. Fisher, Baltimore, or any member of the board of directors.

Lowest Death Rate Recorded for First War Year—The death rate for 1942, the first year of United States participation in the war, was 10.4 per thousand of population, according to a report issued by the Bureau of the Census, Department of Commerce. This rate was slightly lower than the rate of 10.5 per thousand of population in 1941 and was the lowest ever recorded for the United States. Despite the decrease in the total death rate there was an increase in the rate for certain causes of death such as heart diseases, cancer and intracranial lesions of vascular origin. Most of the increase occurred in the diseases characteristic of old age. Cancer claimed 164,400 lives in the United States last year, 3,474 more than in 1941. Substantial reductions in the death rate were recorded for pneumonia and influenza and motor vehicle accidents. The ten leading causes of death and their death rates per hundred thousand of population in 1942 as compared with their rates in 1941 were as follows:

	1942	1941
1 Diseases of the heart	295.2	290.2
2 Cancer and other malignant tumors	122.1	120.2
3 Intracranial lesions of vascular origin	90.2	89.1
4 Nephritis	72.4	75.1
5 Pneumonia and influenza	55.7	63.9
6 Tuberculosis	41.1	44.5
7 Premature birth	25.8	25.1
8 Diabetes mellitus	25.4	25.5
9 Motor vehicle accidents	21.2	30.0
10 Syphilis	12.2	13.3

Southern Surgical Association—The annual meeting of the Southern Surgical Association will be held at the Roosevelt Hotel, New Orleans, December 7-9, under the presidency of Dr. Barney Brooks, Nashville, Tenn. Included among the speakers will be:

Drs. Alfred Blalock and Edwards A. Park, Baltimore, The Surgical Treatment of Experimental Coarctation (Atresia) of the Aorta.
Col. Daniel L. R. Borden, M. R. C. A. U. S., and Dr. Frank McDowell, St. Louis, Neck Dissection for Carcinoma.
Lieut. Col. Burr A. Carter and Major Michael E. DeBakey, M. C., A. U. S., Current Trends in Military Surgery.
Dr. Warren H. Cole and Lewis J. Roszter, A. B., Chicago, Chronic Cystic Mastitis.
Col. Bradley J. Coley and Major George F. Wollgast, M. C., A. U. S., Penicillin Therapy in an Army Hospital.
Lieut. Col. Loyd Davis, M. C., A. U. S., Major John E. Scarff, M. R. C. A. U. S., Major Neil C. Rogers, M. C., A. U. S., and Lieut. Meredith Dickinson, M. R. C. High Altitude Frostbite.

Conference of Professors of Preventive Medicine—The first annual meeting of the Conference of Professors of Preventive Medicine was held in New York, October 11. In a discussion of "New Responsibilities and Opportunities for Departments of Preventive Medicine and Public Health," Dr. Harold W. Brown, dean of the School of Public Health, University of North Carolina, Chapel Hill, and Dr. Jean A. Curran, dean, Long Island College of Medicine, Brooklyn, spoke on "Tropical Medicine," Lieut. Col. Arthur P. Hitchens, M. C., U. S. Army, retired, and Leland W. Parr, Ph.D., Washington, D. C., on "The Military Emergency in General and the Pre-

ence in Medical Schools of A S T (Army) and V12S (Naval) Programs in Particular" and Dr Roscoe R Spencer, chief, National Cancer Institute, Bethesda, Md., "Social and Economic Factors as They Influence Disease Production and Health Promotion." A round table on objectives and methods in the teaching of preventive medicine and public health was also held. The Conference of Professors of Preventive Medicine was organized in St Louis, Oct 30, 1942. It is an informal organization of the men and women who teach preventive medicine in the approved schools of the United States and Canada and aims to promote the better teaching of the specialty through the bringing together of those who do the teaching and the discussion of problems which arise in that teaching. Dr Wilson G Smillie, New York, is president and Dr Parr secretary.

CANADA

Institute of Psychiatry Created at McGill—The Allan Memorial Institute of Psychiatry has been established at McGill University, Montreal Quebec. The new institute a 50 bed hospital which will become the teaching center of a newly organized department of psychiatry in the university's medical school, will be housed in "Ravenscrag" formerly the home of Sir H Montagu and Lady Allan, who presented it to the Royal Victoria Hospital, Montreal. The accommodations will be for patients suffering from early and acute psychiatric conditions. Facilities for intensive treatment are being set up. The project will include laboratories to accommodate the development of research and treatment which are the principal objectives. According to the *American Journal of Psychiatry* the Rockefeller Foundation has made a grant of \$150,000 over an initial five year period to develop the teaching and research facilities of the institute. The provincial government of Quebec has authorized an annual appropriation of \$30,000 for twenty years for hospital maintenance costs, and Montreal citizens have contributed to the project. Dr D Ewen Cameron professor of neurology and psychiatry and director of the department at the Albany Medical College, Albany N Y, has been named in charge of the new department at McGill University Faculty of Medicine serving as the first full professor of psychiatry there and psychiatrist in chief to the Royal Victoria Hospital. He will also be director of the new institute. Dr Cameron was born in Bridge of Allen Scotland, in 1901. He received his medical degree at the University of Glasgow in 1924. He served on the psychiatry staff of the Johns Hopkins Hospital, Baltimore, from 1926 to 1928 teaching during the latter year as an instructor in psychiatry at the medical school. Subsequently he served at the Burgholzli Zurich, and at the Brandon Hospital for Mental Diseases, Brandon Manitoba returning in 1936 to become senior research psychiatrist for the Foundation of Neuro Endocrine Research at the Worcester State Hospital Mass. In 1938 he went to Albany Medical College.

LATIN AMERICA

Health Activities in Latin America—The development of a quinine project is rapidly going forward in Colombia and providing work for hundreds of workers. The discovery of these quinine bearing trees dates back prior to 1878, when Jose Triana a Colombian botanist through his researches discovered these trees in the Bucaramanga area. A paper written by him was subsequently published in a French journal. A commission in 1917 made investigations, but steps were not taken to develop the quinine found there. In 1942 a commission sponsored by the U S Board of Economic Warfare, in collaboration with agencies of the other American republics, sent a mission to Colombia in its program to discover additional hemisphere sources of quinine. It found a stand of trees extending over 700,000 acres just as Triana reported in his article more than fifty years ago.

Tuberculosis Control—Antituberculosis vaccine has been employed successfully for the first time in Colombia with serum donated by the republic of Venezuela. According to the Newsletter of the Health and Sanitation Division Dr Edmundo Medina chief of the department of epidemiology administered the vaccine for the first time in Bogota to 10 infants at the Maternity Hospital. In Ecuador four of the six pavilions originally planned for the tuberculosis hospital in Guayaquil are now finished, except for a few details.

Typhus Fever Report—Serious outbreaks of typhus were reported during July near Cobán, Quezaltenango, Totonicapán, Solola and Tecpan. During 1942 89 cases of the disease were reported by the U S Public Health Service in Colombia. Surveys conducted by a combined U S Military and Naval Commission formed in 1942 to study typhus show that the

disease was present in Bolivia, Chile, Colombia, Ecuador, El Salvador, Guatemala, Mexico, Panama, Peru and Venezuela. Complement fixation tests have proved its presence in Bolivia, Colombia, Ecuador, El Salvador, Guatemala and Peru.

Personal—Dr Thomas B. Phinney, formerly commissioner of public health for Richmond County, Augusta Ga, is chief of the new field party in the Dominican Republic. Dr David Glusker, Yonkers N Y, is the new chief of party in Costa Rica. A plaque was unveiled in the Faculty of Medicine of the University of Mexico, July 13, in honor of Dr Gonzalo Castañeda, first president of the Mexican Academy of Surgery, who has completed fifty years in the practice of medicine.

New Construction—A new hospital on the grounds of the Getulio Vargas Hospital at Alagadico in Fortaleza Brazil was recently completed. Dr Jose Borges de Sales is chief medical officer. The government of Guatemala has approved the construction of a three story 300 bed general hospital to be built on the site of the former "Esperanza" in Guatemala City.

Society News—The conference of sanitary engineers on inter-American service and public health presided over by Dr Eugene P Campbell regional director for Central America and Panama, was held in Managua, October 11-14. The first Pan American Physical Education Congress was held in Rio de Janeiro Brazil, July 19-31. The congress was set up on a permanent basis with a secretary in Peru under the auspices of the department of physical education of Peru. It was agreed to hold the next congress in Mexico City in 1945 according to the *Child*. Prof A M Barriga Villalba has been elected president of the recently established Sociedad de Biología. Other officers include Profs Jose Ignacio Chela and Kaiman Merz, vice presidents, Dr Luis Maria Murillo, treasurer, and Prof J Hernando Ordoñez, general secretary. The official journal of the new group is *Anales* the first number of which recently made its appearance.

FOREIGN

Institute for Typhus Research—The *British Medical Journal* reports that an institute for typhus research named after Emil A von Behring, German bacteriologist, 1854-1917, has recently been opened in Lemberg. The journal announces also that a special typhus institute has been created in Dresden for the "wholesale" preparation of typhus vaccine.

American Award Goes to British Scientist—The Grocery Manufacturers of America has given its 1943 annual award to Sir John Boyd Orr, LL D, director of the Rowett Research Institute, Aberdeen, who, according to *Science*, was largely responsible for improving the nutritive quality of the English diet in the face of wartime food shortages. The presentation ceremony was broadcast on November 4 over a two way transatlantic hookup by the Blue Network at a meeting of the association in New York. Sir John accepted the award over the air from England. He is a member of the advisory committee on nutrition of the Ministry of Health.

International University Sanatorium Proposed—Plans are under way to establish an International University Sanatorium in Switzerland under the auspices of international student organizations the International Union Against Tuberculosis, the League of Red Cross Societies, the International Committee for Intellectual Cooperation and the European Rotary. Half a million Swiss francs have already been granted by the Swiss government to the project. The subscription of "founders' shares" at 25,000 Swiss francs each is now available, entitling subscribers to permanent ownership to one of the beds and membership in the governing body. A recent announcement indicated that 40 of the proposed 208 beds have been taken and that construction will start as soon as 100 shares have been subscribed. The idea for the institution stemmed from the success of the Swiss University Sanatorium in Leysin in the Vaudois Alps, which was opened in 1922 as a place where professors and students afflicted with tuberculosis could obtain the necessary treatment and carry on with some of their studies as well. Dr Louis Vautier director is the original sponsor of the project which was supported by the Swiss universities and the Swiss Federal School of Technology.

CORRECTION

Evaluation of Albuminuria—In paragraph 3 of the directions for determining the significance of albuminuria in selections in the communication by Drs Derow and Stellar in *THE JOURNAL*, October 23 page 503, the word 'supine' should have been used instead of prone.

Oct 2 1955

The Beveridge Plan

At a meeting of the Fever Hospital Medical Service Group of the Society of Medical Officers of Health, Dr A Felix opened a discussion on recent advances in the laboratory control of typhoid and paratyphoid fevers. He referred to the finding of Clugie and Yen in 1938 that strains of the typhoid bacillus could be divided into types by their sensitiveness to specifically adapted anti V_i bacteriophages. The results were as reliable as those obtained in streptococcal or pneumococcal infections with the established serologic tests. More recently

141x and Calloz had found that the bacteriophage technic could be applied to strains of the paratyphoid B bacillus. Anti Vi phages of *Salmonella paratyphi* B could be adapted to develop a high degree of specificity for particular strains. So far, four different Vi phage types of *S. paratyphi* B had been identified and more than 90 per cent of the strains isolated from patients and carriers in Britain during the past three years were found to belong to those four types. The new typing method was found to be an indispensable laboratory aid to investigation of sporadic cases or outbreaks of typhoid and paratyphoid fever. The detection of a chronic carrier was usually difficult, though the methods of isolating the bacilli had been greatly improved by the introduction of refined culture mediums. In all our recent outbreaks of paratyphoid B fever those responsible for spreading the infection were temporary excretors. The true culprits were the chronic carriers, and they escaped detection. The test it was reported, could be used to detect chronic carriers among recovered patients who otherwise might be discharged from the hospital because they excreted bacilli intermittently. A decreasing Vi titer would indicate temporary excretion, a steady or rising one a possible carrier state.

Reform in the Training of Psychiatrists

The means provided for the training of psychiatrists are felt to be unsatisfactory at present. In only a few of the medical schools is the student given a proper introduction to the subject and the standard for the diploma in psychologic medicine is low in general. To remedy this condition a committee provided over by Sir Walter Langdon-Brown has drawn up a program which has been published. The committee considers that graduates of one year should not be allowed, as at present, to emerge as fully equipped specialists. Four years' postgraduate training is recommended as the minimum for the diploma. Also the aspirant should not rush straight from medical school into specialized training but should first obtain experience in general medicine for at least one year in hospital or general practice. The committee further recognizes that for full understanding of psychiatry a year or two should be spent in close contact with mental disorders in their worst forms. The creation of psychiatric clinics in general hospitals, valuable as it is, does not remove the need for residence in a mental hospital as part of the psychiatrist's training; the committee feels. The ideal training should include both

Rehabilitation of the Amputated

Members of the Allied Ex-Service Men's Provisional Committee, drawn from fourteen countries, recently paid a visit of inspection to Roehampton Hospital, the great center for supplying artificial limbs. During this war 2,330 amputations resulting from enemy action and comprising service patients and civilian men, women and children have been dealt with. The visitors met a 14 year boy from Malta whose legs had both been amputated after an air raid. He was wheeling himself in a chair and had just been swimming. He had arrived in the last month to be fitted with artificial limbs. The wonderful work for the limbless done at Roehampton involves rehabilitation on the mental no less than on the physical plane. A gunner sergeant who lost his right arm above the elbow in Libya eighteen months ago wheeled a heavy barrow and then wielded a pick vigorously to break up a lump of concrete. An instructor who lost his left arm below the elbow showed how, with special appliances, he can use that arm to saw, drive nails and handle a plane. A young girl with an artificial leg the consequence of a German bomb, mounted, rode and dismounted from a bicycle with every appearance of naturalness. Another cyclist, a man, had two artificial legs. He not only rides considerable distances but, like others among the ex-patients, stands long hours at a bench every day.

BUENOS AIRES

(From Our Regular Correspondent)

Oct. 1, 1943

The Heart in Emphysema

The Brazilian Academy of Medicine recently awarded its international prize to Drs Elyser Magalhães, Egídio S Mazzei and Jorge M Remolar, all of Buenos Aires, for their report of a clinical and experimental study on the heart in emphysema. The authors carried on their work in the Instituto de Investigaciones Aplicadas a la Patología Humana of the National Academy of Medicine of Buenos Aires. They found that the conflicting opinions previously given by several authors on the clinical effects on the heart during the course of emphysema were due to lack of differentiation of the circulatory changes caused by the bronchogenic and thoracogenic types of emphysema. Bronchogenic emphysema is the cause of chronic pulmonary heart disease, from which congestive cardiac insufficiency develops. Thoracogenic emphysema causes cardiac disorders which mainly result from coronary sclerosis.

The authors proved the interpretation of their clinical and anatomic studies by experiments on dogs. Electrocardiograms of patients with bronchogenic emphysema show preponderance of the right half of the heart and pulmonary P wave, whereas those of patients with thoracogenic emphysema show the changes proper in coronary insufficiency. Special attention is given by the authors to reports on the subject in the American literature, mainly those of Korentz and Alexander, Christie, McIntosh and Pasne.

Bullous Emphysema Caused by Bronchial Tumors

Drs M R Castex, E S Mazzei and J M Remolar of the Instituto de Investigaciones Físicas Aplicadas a la Patología Humana have reported the results of their investigations on the production of bullous emphysema by bronchial tumors. A certain number of bronchial tumors, as a result of a valvular obstruction of the bronchus, lead to the production of areas of bullous emphysema. This is often the earliest radiologic sign of the bronchial neoplasm and gives a clue to the diagnosis of some cases of bronchial tumors before any shadow is visible by x ray.

Health of the Argentine Army

The minister of war recently presented a report in which he stated that the health of the Argentine army is extremely good. The morbidity of infections and contagious diseases is negligible. The morbidity of epidemic parotiditis is 2 per thousand and that of measles, diphtheria, pneumonia and rheumatic fever is 1 per thousand. Cases of typhoid and malaria are rare. Army examinations of soldiers for tuberculosis are performed frequently.

Special mention of venereal disease does not appear in the report. Success in preventing infections and the good health of soldiers are attributed to the prophylactic measures used in the army: good food and proper hygiene.

Food of Argentine Soldiers

The minister of war recently reported on the rations of soldiers which are based on the cost of living in the different regions of the country. The higher ration allowances are given to soldiers in the southern region. In all regions the daily menu has the proper nutritional value and is well selected and varied during the week. Army physicians are consulted in connection with nutritional values in the preparation of the various diets. Good meat of all kinds, milk, bread, vegetables, cheese, fruits, rice, sugar and other good foods are given in abundance to soldiers. The kitchens and dining rooms of all quarters are modern and large and have proper lighting and ventilation.

Partial Hepatectomy and Pregnancy

Drs Erico Fels and I de Landa have reported to the Argentine Society of Biology on the effect of partial hepatectomy in animals on the course of pregnancy. They concluded that extirpation of one third of the liver does not prevent the normal course of pregnancy, while the excision of one half or more of the structure is followed by immediate termination of pregnancy. Nine days after removal of half of the liver, pregnancy can again occur and proceed normally, owing to the liver's remarkable power of regeneration. Administration of deoxycorticosterone or progesterone had no effect on the results.

Public Health in Paraguay

Public health in Paraguay has recently shown improvement. The Department of Hygiene has increased its work, especially in epidemiology. The campaigns against schistosomiasis, trichinosis, malaria, typhoid and smallpox have been intensified. A division for prevention and therapy of venereal diseases was recently established, with clinics and dispensaries for free medical care and drugs. Medical centers are to be constructed with a sum of \$1,000,000 that the government of the United States allotted to the country through the Inter-American Department of Public Health. The project will include buildings for all the various activities of public health, a central pharmacy, the Department of Hygiene and branch offices of the Department of Public Health, a sanatorium for tuberculous patients and a leprosarium. Several hospitals are to be enlarged and improved.

Physicians in Paraguay

According to the 1942 statistics published by the Ministry of Public Health of Paraguay, there are in Paraguay 229 physicians, 73 dentists, 198 pharmacists, 7 chemists and 47 midwives.

Physicians in Uruguay

The number of physicians in Uruguay is estimated in a recent statistical survey to be 1,635, 1 for each 1,346 persons. There are 1,177 physicians in Montevideo, 1 for each 595 persons, and outside the capital there are 458 physicians, 1 for each 3,275 inhabitants.

Poliomyelitis in Chile

In a study of infantile paralysis in Chile, Dr Agustín Inostroza reported that only 99 cases were observed in a period of five years (1937-1941). Eighty-four of the cases occurred in children under 2 years of age, only 1 case occurred in the age group from 5 to 10 years. No case was observed in persons above 10 years of age. Of the 99 cases reported, 98 presented motor disturbances in the lower extremities, and in 11 cases the paralysis also involved the upper extremities. In one third of the cases the paralysis was bilateral.

Marriages

- THOMAS GRIGSBY HERBERT JR, Charleston, S C, to Miss Miriam Pope of Dade City, Fla, in Jacksonville, Fla, July 23.
ROBERT JOHN FLOODY, Nutley, N J, to Miss Victoria Lillian Stanbury of Campbellford, Ont, Canada, in September.
ROBERT JAMES ALLEN, Elizabethton, Tenn, to Miss Jeanette Merck of Gainesville, Ga, in Rossville, Ga, recently.
THEODORE JACKSON BENDER JR, Mobile, Ala, to Miss Agnes Gavin of Memphis, Tenn, September 26.
WEIR MITCHELL TUCKER, Richmond, Va, to Miss Linden Crawford of Rosemont, Pa, October 2.
WILLIAM HUGHES EVANS to Mrs Elizabeth Miller Williams both of Richmond, Va, September 29.
DANIEL A BRODY, Youngstown, Ohio, to Miss Barbara Ann Murray of Lorain, recently.
GAVIN BYRON HODGE to Miss Katie Adams, both of Durham, N C, September 22.
JOSEPH A WALSH, Olyphant, Pa, to Miss Wynne Campbell of Baltimore, October 30.

200 200 200 200

Colonel Halloran was born in Cambridge, Mass. Aug. 4, 1884. He received his bachelor of art degree cum laude from Dartmouth College Hanover, N. H. in 1917, then graduated at Columbia University College of Pharmacy and Surgerons New York in 1920. From his internship at the New York City Hospital he went to the University of Maryland to study for his M. D. degree. He received his M. D. degree from the Johns Hopkins School of Public Health, Baltimore. He was a resident physician at the New Hampshire State Hospital and then joined the faculty as a staff physician, senior lecturer and chairman of the department of medicine at the University of Maryland. He has been active in research at the University of Maryland and has been instrumental in the establishment of the Department of Preventive Medicine. In 1945 Colonel Halloran

The death of Colonel Halloran again focuses attention on the tremendous burden carried by physicians as a contribution to the winning of the war. Certainly his untimely death, so young, from a failure of the heart to meet the stress placed upon it is a great loss to medicine and to the nation.

Charles Watts Flynn, Dallas, Texas, University of Pennsylvania School of Medicine, Philadelphia, 1911, instructor in anatomy at the University of Pittsburgh, 1912-1913, associate professor of surgery at the Baylor University College of Medicine from 1914 to 1927, professor of operative surgery from 1927 to 1930, professor of clinical surgery from 1930 to 1937, professor of surgery from 1937 to 1941 and since the latter date emeritus professor, honorary professor of surgery at the Southwestern Medical Foundation School of Medicine, specialist certified by the American Board of Surgery, member of the State Medical Association of Texas member and formerly vice president of the Southern Surgical Association, fellow of the American College of Surgeons, formerly chief surgeon at the Baylor University Hospital, visiting surgeon, St Paul's, Methodist and the Medical Arts hospitals, died August 13, aged 59, of cerebral hemorrhage

COL ROY D HALLORAN, M C, A U S, 1894-1943

Halbert Greenleaf Stetson & Greenfield, Mass. College of Physicians and Surgeons, Baltimore, 1895, member of the House of Delegates of the American Medical Association in 1904 from 1912 to 1914 and from 1916 to 1932, past president of the Massachusetts Medical Society, Franklin County Medical Society, New York and New England Association of Railway Surgeons and the Connecticut Valley Medical Association, member of the New England Surgical Society, fellow of the American College of Surgeons, medical examiner for Franklin County member of the city board of health from 1909 to 1912, chairman of the school board for many years president of the board of trustees, the hospital corporation and staff, Franklin County Hospital, on the staff of the Warren Memorial Hospital, Montague City, served as president of the chamber of commerce, died September 15, aged 75, of congestive heart disease.

George Van Amber Brown & McAllen, Texas. Detroit College of Medicine, 1894, member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, assistant secretary from 1923 to 1928, first vice president 1923-1924 and president 1928-1929, president of the Wayne County (Mich.) Medical Society, 1927-1928, of the Northern Tri State Medical Association in 1918 and of the Hidalgo Starr Counties Medical Society in 1940, fellow of the American College of Surgeons and a member of the board of governors from 1930 to 1932, formerly head of the German Polyclinic, chief of staff, senior surgeon and chief urologist, Highland Park General Hospital, and senior gynecologist at the Providence and St. Joseph's Mercy hospitals, all of Detroit, surgeon, McAllen Municipal Hospital, died September 19, aged 73, of angina pectoris.

Edwin Lee Miller, Kansas City, Mo., Harvard Medical School, Boston, 1911, member of the Missouri State Medical Association and president, 1935-1936, member of the Western Surgical Association and the Southern Medical Association, specialist certified by the American Board of Surgery, first lieutenant in the medical corps of the U. S. Army during World War I, a founder and member of the executive staff, St. Luke's Hospital, on the staff of St. Mary's Hospital and chief of the surgical staff of the Kansas City General Hospital for many years, consulting surgeon, Missouri Pacific Railway, received the Distinguished Alumni Award of Merit from the University of Missouri, Columbia, in 1938, died October 6, aged 56, of coronary disease with myocardial infarction.

Raymond Ernest Senecal & New Bedford, Mass., Boston University School of Medicine 1917, appointed a member of the Public Health Council in July 1943, president of the New Bedford Medical Society, school physician, served during World War I in 1929 retired as a major in the medical reserve corps of the U. S. Army, on the staffs of St. Luke's and Union hospitals, New Bedford Acushnet Hospital Acushnet, and St. Anne's Hospital, Fall River, physician for the board of public welfare for a number of years member of the Franco-American Civic League Franco-American Historical Society New Bedford Civilian Defense Council Massachusetts Committee on Public Safety and the American Executives Club died August 24, aged 51, of coronary occlusion.

John Butler & Minneapolis, University of Minnesota College of Medicine and Surgery, Minneapolis 1903, associate professor of dermatology at his alma mater, specialist certified by the American Board of Dermatology and Syphilology, member of the American Dermatological Association and the American Academy of Dermatology and Syphilology, major in the medical officers reserve corps, in charge of the department of dermatology and urology at Camp Lewis, Washington, from 1917 to 1919, colonel in the medical reserve corps not on active duty, at one time assistant city physician, on the staffs of the University St. Mary's St. Barnabas Northwestern General, Lathamhurst and Abbott hospitals, died September 18, aged 66, of coronary disease.

Ivin Sickels, West Nyack, N. Y., University of the City of New York Medical Department 1883, assistant professor of chemistry and physics at the Cornell University Medical College New York, from 1898 to 1908, professor of natural history and subsequently professor of geology at the College of the City of New York where he taught from 1875 until his retirement in 1923 at which time he was appointed professor emeritus, instructor in chemical laboratory from 1882 to 1887, lecturer in chemistry and physics from 1887 to 1891 and assistant professor of chemistry and physics from 1891 to 1898 at the University Medical College New York, died August 5, aged 80, of pneumonia.

John Milton Berger & Chicago. College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois 1908, formerly instructor in surgery and assistant in

clinical surgery at his alma mater and instructor and assistant professor of surgery at Loyola University School of Medicine served as a major in the medical corps of the U. S. Army in France and Germany during World War I, on the staffs of the Garfield Park Community and St. Anne's hospitals, formerly attending surgeon at the Frances Willard Hospital died at his home in Oak Park, Ill., September 23, aged 60, of coronary thrombosis.

John Blair Fitts, Richmond, Va., Medical College of Virginia, Richmond, 1914, assistant professor of orthopedic surgery at his alma mater, member of the Medical Society of Virginia and the American Academy of Orthopedic Surgeons in 1936, elected president of the Virginia Orthopedic Society, fellow of the American College of Surgeons, served in France during World War I, assistant orthopedist Hospital Division, Medical College of Virginia, orthopedic consultant at the Retreat for the Sick and the Stuart Circle Hospital, where he died August 19, aged 53, of leukemic leukemia.

Julius Hilton Sure & Milwaukee, College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1903, specialist certified by the American Board of Obstetrics and Gynecology, Inc., visiting obstetrician and gynecologist, Columbia Hospital, attending obstetrician and gynecologist at the Johnston Emergency Hospital, chief of the obstetric and gynecologic clinic and consultant in obstetrics and gynecology at the Mount Sinai Hospital where he died August 19, aged 63, of acute myocardial infarction, coronary thrombosis and arteriosclerosis.

James Murice White & Gary, Ind., Northwestern University Medical School Chicago 1926, past president of the Lake County Medical Society and the Tenth District Medical Society, councilor of the Tenth District from 1938 to 1942, past president of the board of health of Gary, served as examining physician for Gary Draft Board number 9 and as a member and secretary of the Lake County Selective Service Appeal Board on the staffs of the St. Mary's Mercy Hospital and the Methodist Hospital, where he died August 5, aged 45, of coronary thrombosis.

Dix Henry Alverson, Shreveport, La., Memphis (Tenn.) Hospital Medical College 1902, member of the Louisiana State Medical Society, died suddenly September 7, aged 63, of coronary occlusion and nephritis.

Lillian Bryan Askenstedt, Louisville, Ky., Southwestern Homeopathic Medical College and Hospital, Louisville 1904, formerly lecturer at her alma mater and the Deaconess Hospital, died September 25, aged 75, of coronary occlusion.

Clarence Allen Baer & Milwaukee, Johns Hopkins University School of Medicine, Baltimore 1905, specialist certified by the American Board of Dermatology and Syphilology, served on the British and French fronts with the Red Cross during World War I and for devotion to duty was decorated by the French government, at one time chief of staff at the Milwaukee Children's Hospital, died September 15, aged 63, of coronary thrombosis and myocarditis.

William H. Barnum, Fremont, Mich., Saginaw (Mich.) Valley Medical College, 1902, member of the Michigan State Medical Society, secretary and past president of the Newaygo County Medical Society, chairman of the Newaygo County Selective Service Board, past president of the chamber of commerce, a director of the Home State Bank of Fremont, died suddenly in Baldwin September 4, aged 70, of cerebral hemorrhage.

Johnson Lorenzo Bean, Norway, Maine, Tufts College Medical School, Boston, 1933, member of the Maine Medical Association and the New England Pediatric Society, served on the staff of the Maine General Hospital, Portland, began extended active duty as a captain in the medical corps Army of the United States on Oct. 15, 1942, honorably discharged because of physical disability on May 12, 1943, died August 10, aged 37, of coronary occlusion.

Hector Emile Bernadas & New Orleans. Medical Department of Tulane University of Louisiana, New Orleans 1902, past president and vice president of the Orleans Parish Medical Society, councilor of the First District Medical Society, president of the staff Hotel Dieu Sisters Hospital, died suddenly September 22, aged 64, of coronary thrombosis.

Samuel M. Bloomstein, Nashville, Tenn., University of Nashville Medical Department 1896, member of the Tennessee State Medical Association for many years professor of clinical pediatrics at the Vanderbilt University School of Medicine, formerly a member of the city board of education, served on the board of directors of the Davidson County Tuberculosis Hospital for sixteen years, died September 24, aged 73, of endocarditis.
